▮ Economic conditions

Underlying trends

German economic activity is likely to have more or less stagnated in the second quarter of 2022. The elimination of most coronavirus mitigation measures lent a strong boost to previously beleaguered service providers and the related consumption expenditure. Hotel and restaurant sector revenues rose steeply on an average of April and May compared with the first quarter. According to the ifo Institute, the business situation of enterprises in the services sector (excluding trade) improved significantly overall in the spring. However, surging inflation weighed on households' purchasing power; their propensity to consume was also adversely affected by uncertainty regarding the future energy supply. The consumer climate index calculated by the market research institute GfK fell to a record low. The poor sentiment among consumers was reflected in substantially lower sales in retail and motor vehicle trade. According to ifo Institute surveys, shortages of materials and labour weighed on activity in the construction sector. Industry continued to be constrained by supply bottlenecks and, moreover, suffered from high uncertainty about future economic developments and from weaker demand – albeit starting from a high level. As a result, it was probably unable to maintain its first-quarter production levels. The considerable cutbacks in Russian gas deliveries since mid-June have been a major drag on enterprises and households, with gas prices skyrocketing as a result. This is also weighing on the outlook. In the current quarter, GDP growth is, from today's perspective, likely to be somewhat weaker than expected in the baseline scenario of the Bundesbank's June 2022 projection.[1]

Industry

In May 2022, industrial production[2] was up slightly on the month after seasonal adjustment[3] (+½%). It had already recovered somewhat in April from the distinct decline in March. This also applies to the production of motor vehicles and motor vehicle parts, which had previously contracted particularly steeply. According to the German Association of the Automotive Industry, the number of passenger cars manufactured rose slightly in June as well. Survey results provided by the ifo Institute and S&P Global suggest that supply bottlenecks in industry have now receded somewhat following the considerable exacerbation in March. On an average of April and May, industrial production nevertheless remained markedly below its first-quarter level (-1¼%). Enterprises produced distinctly fewer intermediate and capital goods than in the previous quarter. In the case of intermediate goods, the decline was particularly pronounced in the area of other non-metallic mineral products. This could have something to do with the sector's pronounced dependence on gas and surging gas prices. By contrast, consumer goods production contracted only slightly. However, isolated sectors, such as the pharmaceutical industry, experienced sharp declines in production. Overall, industrial production remained significantly below the level prior to the outbreak of the coronavirus pandemic (-4½%).

---

1 See Deutsche Bundesbank (2022). However, according to the current assessment, the German economy is likely to be much closer to the baseline scenario than the adverse risk scenario described by the Bundesbank's economists.
2 The time series for industrial production has been revised significantly. For example, the data for the economic sectors and aggregates as from January 2021 were reworked as part of the regular annual revision. In addition, the method used to calculate the production index for the manufacture of motor vehicles was changed. The results for this sector were revised back to January 2015. See Federal Statistical Office (2022).
3 Seasonal adjustment here and in the remainder of this text also includes adjustment for calendar variations, provided they can be verified and quantified.

Deutsche Bundesbank

In May 2022, industrial new orders remained constant in seasonally adjusted terms, after declining for three consecutive months. If large orders are excluded, however, they fell slightly. On an average of April and May, new orders decreased steeply compared with the first quarter (-4¾%) and, excluding large orders, the decline was distinctly weaker (-2¾%). Manufacturers of capital goods received considerably fewer orders. The mechanical engineering sector saw a slight uptick in orders, however. Demand for intermediate goods was down significantly. By contrast, orders for consumer goods picked up substantially, although demand for pharmaceutical products was considerably lower. Broken down by region, new orders from non-euro area countries dropped sharply and those from euro area countries considerably. Domestic orders dipped somewhat, too.

Industrial new orders constant

In May 2022, nominal industrial sales rose substantially on the previous month after seasonal adjustment (+3½%). On an average of April and May, they grew markedly (+2%) compared with the first quarter, although this was attributable to steep price increases. Broken down by region, nominal sales were up in the euro area and in Germany, in particular. By contrast, sales in non-euro area countries fell somewhat. Broken down by sector, sales of intermediate and consumer goods rose sharply, while slightly fewer capital goods were sold. After seasonal adjustment, nominal exports of goods were markedly higher in May 2022 compared with the previous month (+1½%). The increase was somewhat smaller after price adjustment (+1%). Nominal exports to the Russian Federation were up substantially but remained quite considerably below the level prior to the outbreak of the war in Ukraine. On an average of April and May, nominal exports of goods rose steeply compared with the first quarter (+5%). After price adjustment, however, the increase was significantly lower (+1¼%). Real exports of goods to euro area countries improved markedly, while those to non-euro area countries were up only slightly. May saw a steep rise in nominal goods imports after seasonal adjust-

Industrial sales up sharply on account of high price increases; rise in exports and imports

ment (+3½%), and even after price adjustment there was a clear increase (+2½%). As a result of the sanctions, nominal imports from Russia fell considerably once again, however. Taking the average for April and May, nominal imports of goods were up sharply compared with the first quarter (+9½%). This growth was significantly lower after price adjustment due to surging import prices (+3¼%). The increase is attributable primarily to imports from non-euro area countries, although slightly more goods were imported from the euro area, too. Broken down by product category, imports of chemical products, in particular, were higher.

Construction

Slight rise in construction output

After adjustment for seasonal variations, output in the construction sector increased slightly in May 2022 when compared with the previous month (+½%). On an average of April and May, however, sales were down markedly on the first quarter (-2%), with production in the main construction sector considerably below its first-quarter level. By contrast, the finishing sector saw only a slight drop in output. One factor contributing to the decline in construction output to a certain extent is likely to have been the favourable weather in the first quarter, which has now led to a countermovement. In addition, shortages of labour and materials probably intensified considerably compared with the winter quarter as is indicated by ifo Institute surveys among enterprises in the main construction sector. Signs of relief have been appearing recently, however. New orders in the main construction sector declined substantially in April – the latest month for which data are available – compared with the first quarter. Nevertheless, the order situation in construction is expected to be favourable. Although the reach of the order books as determined by ifo Institute surveys declined slightly in June, it remained high in a long-term comparison. Utilisation of equipment declined for the fourth consecutive month, but was still well above its long-term average.

Labour market

The seasonally adjusted rise in employment in May, in which the number of persons in employment increased by 35,000, was once again less pronounced than in the previous month. In addition to the relatively weak spring pick-up following a mild winter, increasing strains from the war on Ukraine and the – in part related – high energy prices and supply bottlenecks for intermediate goods are likely to be making themselves felt. However, it is also becoming increasingly difficult to fill vacancies in some areas of the services sector. According to an initial estimate by the Federal Employment Agency, the increase in employment subject to social security contributions was already rather weak in April. The use of cyclical short-time working declined further in April, with the number of new registrations for short-time work, in fact, exceptionally low in June. Other leading indicators of enterprises' hiring intentions are pointing to increasingly weaker job growth in the coming months.

Employment growth less pronounced than in recent months

Following an almost uninterrupted decline for two years, registered unemployment rose steeply in June. In seasonally adjusted terms, the number of unemployed persons increased by 133,000 to 2.42 million. The unemployment rate was up by 0.3 percentage point to 5.3%. This can be explained mainly by the incorporation of Ukrainian refugees into the social security system with effect from June. Once they have received benefits for three months under the Act on Benefits Granted to Persons Seeking Asylum *(Asylbewerberleistungsgesetz)*, they are recorded as unemployed if they are classified as being fit and available for work. As a result, in the vast majority of cases, these persons now receive the basic allowance for job seekers. According to the Federal Employment Agency, however, unemployment rose slightly even without the effect described above. This is likely to be due to the rather weak spring rebound and active labour market policy measures mitigating unemployment to a smaller ex-

Unemployment up sharply due to Ukrainian refugees

tent.[4] It is also possible that unemployment might continue to rise over the coming months. The IAB unemployment barometer moved from positive to negative territory in June; however, the informative value of this indicator in economic terms is impaired by refugee movements.

Prices

Surging natural gas prices

Prices on the international energy markets in June 2022 were characterised by countervailing trends. Brent crude oil cost just under US$110 per barrel at last report, and thus slightly lower than at the end of May. By contrast, natural gas prices in Europe surged once again. This is likely to be largely due to supply shortages and concerns that Russia might halt gas deliveries altogether. The cost of a megawatt hour doubled from just over €80 at the beginning of June to around €170 at the end of the period under review.

Price pressures at upstream stages remain high

Overall, price increases at the upstream stages of the economy remained near the all-time high levels of the preceding months. Import prices increased by 31% in May compared with the previous year, just under 1 percentage point less than in March and April. At the domestic producer level, prices were up by 34%, which was roughly in line with the April figure. At both stages, price pressures for energy and intermediate goods were slightly weaker, while prices of consumer goods and capital goods once again accelerated.

Inflation rate down in June, mainly due to €9 ticket

The rate of consumer price inflation fell somewhat from a very high level as this report went to press. In June, the Harmonised Index of Consumer Prices (HICP) rose by 8.2% on the year, 0.5 percentage point lower than in May.[5] This was mainly due to public transport becoming significantly cheaper as a result of the temporary introduction of the €9 ticket.[6] Seasonally adjusted month-on-month inflation, at -0.1%, was likewise negative at the end of the period under review. Although energy prices continued to rise very sharply, inflation did not in-

crease any further. This is likely to have been due, at least in part, to the temporary fuel rebate.[7] By contrast, food price inflation continued to accelerate sharply, while price pressures for industrial goods remained unchanged at their high level. The inflation rate is set to remain high over the next few months. It could even climb further in September with the expiry of temporary relief measures. However, the future trajectory of the energy commodity markets is very uncertain, especially with regard to natural gas deliveries from Russia. The risks to the price outlook are clearly tilted to the upside.

■ Public finances[8]

Local government finances

Deficit down significantly at start of year and largely covered by reserves

Local governments (core budgets and off-budget entities) closed the first quarter of this year with a seasonal deficit, as usual. At €5½ billion, it was €3½ billion lower than in the first quarter of 2021. Local governments financed €2 billion of the deficit by taking on new debt (according to the provisional debt statistics). They were able to cover the lion's share by making recourse to the reserves, which stemmed – in part – from the high surplus in the final quarter of 2021.

---

4 See Statistics provided by the Federal Employment Agency (2022), p. 13.
5 The national consumer price index (CPI) showed an increase of 7.6%, compared with 7.9% in May.
6 The effects of the €9 ticket can be seen in the HICP component "Combined passenger transport" (0735). Here, prices fell by 62.9% on the year in June, after having risen by as much as 1.7% in May. Taking into account the current HICP weight of the sub-component, which stands at 1.1%, the HICP rate in June was dampened by around 0.7 percentage point.
7 In early June, the bulk of the fuel rebate is likely to have been passed through to consumers. In the course of the month, the effect of the fuel rebate was probably then overshadowed by fluctuations in the price of crude oil as well as in the exchange rate.
8 In the short commentaries on public finances, the emphasis is on recent outturns. The quarterly editions of the Monthly Report (published in February, May, August and November), by contrast, contain an in-depth description of public finance developments during the preceding quarter. For detailed data on budgetary developments and public debt, see the statistical section of this report.

Strong revenue growth, mainly from local business tax, …

Revenue rose very sharply on the year, by 12% (+€7 billion). At 26%, tax receipts even grew more than twice as strongly (+€4½ billion). After deducting shares accruing to other government levels, local business tax – a large revenue item – increased by 25%. Local governments in Rhineland-Palatinate, in particular, benefited from this, as a vaccine manufacturer is based in this federal state. Local government shares in income tax doubled, rising by €1 billion. This is likely to be related to state governments' final settlements for 2021. Transfers from state government also saw strong growth (+7%, or €2 billion). Receipts from fees went up by 11%. Protective pandemic measures are likely to have had less of a restricting effect on facilities' operations than in the same quarter of the previous year.

… exceeded significant rise in expenditure

Expenditure increased significantly, by 6%. Personnel expenditure climbed particularly sharply (+8%), partly on account of a special effect in Baden-Württemberg. Other operating expenditure also rose substantially (+7%). Spending on social benefits, by contrast, increased only moderately, at 2%. On the one hand, the public long-term care insurance scheme has put a limit on the co-contribution rate of care recipients in care homes since the beginning of the year, easing the burden on social assistance. On the other hand, spending on benefits for asylum seekers increased. Expenditure on refugees from Ukraine probably only started to increase close to the end of the quarter. Fixed asset formation rose by 3½%. This was mainly attributable to construction investment (+5%). The growth in this and other operating expenditure is likely to broadly reflect strong price increases.

Prospect of local government surplus for year as a whole, but uncertainty is great

As things currently stand, a surplus is to be expected again for the year as a whole. For example, the March projection issued by the Federal Ministry of Finance for the Stability Council – updated to reflect the May tax estimate – suggests a similarly high surplus as in 2021 (+€4½ billion). Additional central government funds of €2 billion are intended to cover the

Local government fiscal balance

€ billion
Source: Federal Statistical Office.
Deutsche Bundesbank

additional costs incurred by local governments for spending on refugees from Ukraine. However, uncertainty is great, with high energy prices being a key factor. These also weigh on local government via local utilities companies; aside from lower profit distributions, local authorities may also have to step in to offset losses, under certain circumstances. The macroeconomic risks mainly affect local government through volatile local business tax, which is a large revenue item. A fundamental reform of local government finances remains advisable in order to ensure stable and commensurate funding of local government budgets.[9] This seems particularly important in order to enable governments to reinforce their infrastructure.

9 For more information on starting points for securing stable local government finances, see Deutsche Bundesbank (2021).

Finances of the statutory health insurance scheme*

Year-on-year percentage change

Deutsche Bundesbank

Statutory health insurance scheme

SHI scheme: deficit in the first quarter, deterioration solely due to one-off effects

The statutory health insurance (SHI) scheme (comprising the health insurance institutions and the health fund) recorded a deficit of just over €2 billion in the first quarter of 2022. It had posted a slight surplus in the first quarter of 2021.[10] Excluding positive one-off effects, however, the deficit would have been somewhat higher last year than in the current year.

The health fund posted a deficit of just over €2 billion in the first quarter of 2022. A small sur-

plus was recorded in the same quarter of the previous year, which was due to pre-funding by central government. Contribution receipts grew by just over 4½% compared with the same quarter last year. Around one-half of a percentage point of this was attributable to the slight increase in the average supplementary contribution rates. The fund also received special grants of €9½ billion from central government for its pandemic-related special expenditure in the first quarter, not only on the very substantial expansion of public coronavirus tests, but also for financial assistance to hospitals totalling €4 billion and vaccination costs of €1½ billion. The health fund's other expenditure rose steeply, by 7%. This was driven by the fact that central government increased its annual transfers to the health insurance institutions in order to stabilise the supplementary contribution rates.

Health fund: deficit of €2 billion

As in the same quarter of the previous year, the health insurance institutions achieved a largely balanced result. Total revenue saw strong growth of 6½%, particularly on account of higher central government funds. The health insurance institutions' expenditure also increased by 6½%, including a 6% rise in spending on benefits. Particular growth was seen in those areas where the previous year's figures had been depressed on account of the pandemic. Expenditure on remedies and therapeutic appliances (+14%) and pharmaceuticals (+6½%), above all, rose strongly. Spending on hospital treatment – a major expenditure item – also climbed markedly, by 4½%.[11] Expenditure on medical treatments increased by a more moderate 2½%, following high growth in the previous year. Administrative expenditure grew by a very substantial 18%. Adjusted for higher pension

Health insurance institutions: balanced result

---

10 In 2021, reserves of €8 billion were redistributed among the institutions via the health fund. The associated payment flows did not influence either the financial situation of the SHI scheme as a whole or that of its two constituent parts taken in isolation. The revenue and expenditure developments described in the following are therefore adjusted for these payment flows.

11 Together with the aforementioned assistance from the health fund, payments from the SHI system to hospitals thus rose strongly by 8% at the start of the year.

provisions, however, it rose only to a limited extent. Excluding higher pension provisions, the institutions recorded a modest surplus.

2022: Health fund could close in balance, and …

In its autumn 2021 forecast, the group of SHI estimators assumed a deficit of €2 billion in the SHI system for 2022 as a whole (including the total additional central government grant to the health insurance institutions in the amount of €14 billion). The deficit was expected in the health fund: in the current year, it will pass on €2 billion from its reserves to the institutions. From the current perspective, by contrast, it seems the health fund could perform better, achieving a balanced result. In view of developments to date, for instance, revenue could be considerably higher than expected. However, there are substantial macroeconomic risks with regard to the second half of the year.

… health insurance institutions could record a surplus

Given an unchanged overall contribution rate, the group of SHI estimators anticipated a balanced result for the health insurance institutions. The financial resources from the health fund's reserves and the additional central government grant closed a funding gap of €16 billion. From the current perspective, the health insurance institutions could also perform better, thus recording a surplus. Expenditure could be somewhat lower than expected back in the autumn, for instance. Furthermore, the actual average supplementary contribution rate is just under 0.1 percentage point higher than previously anticipated.

High structural deficit and increasing expenditure pressure; however, predominantly temporary measures announced by health minister

The statutory health insurance scheme is set to face considerable challenges over the coming years, however. It is already structurally underfunded at present. This is likely to be exacerbated in the future as expenditure tends to rise more strongly than income subject to contributions. A financial reform of the statutory health insurance scheme is currently being discussed that would entail the predominantly structural deficit of 1 contribution rate point in 2023 (equivalent to around €16 billion) being covered with a combination of measures. The Federal Minister of Health anticipates an increase in the

average supplementary contribution rate of 0.3 percentage point. In order to limit contribution rate rises on this scale, Federal Government plans to make a one-off payment of an additional €3 billion, including a loan of €1 billion by the end of 2026. Available health fund and health insurance institution reserves are also to be used. In total, these reserves are roughly twice as high as the special funds from central government. Various savings on the benefits side could, for a time, provide as much relief as the special funds from central government. Overall, this will close the expected financing gap next year. However, as the measures announced are mainly temporary in nature, the government would just be putting off taking necessary action.

Securities markets

Bond market

At €137.6 billion, gross issuance in the German bond market in May 2022 was up slightly on the previous month's figure (€129.0 billion). After deducting redemptions, which were lower than in the previous month, and taking account of changes in issuers' holdings of their own debt securities, net issuance of domestic debt securities came to €23.9 billion. The outstanding volume of foreign debt securities in Germany rose by €0.7 billion during the reporting month, boosting the outstanding volume of debt instruments in the German market by €24.6 billion overall.

High net issuance in the German bond market in May 2022

The public sector issued debt securities to the tune of €14.9 billion net in the reporting month, compared with €0.2 billion in April. On balance, central government was the main issuer of new securities (€13.9 billion), placing above all 10-year and 30-year Federal bonds in the market (Bunds: €8.5 billion and €4.0 billion, respectively), but also two-year Federal Treasury notes (Schätze: €6.2 billion) and five-year Federal notes (Bobls: €3.6 billion). This contrasted with redemptions of Treasury dis-

Deutsche Bundesbank

count paper (Bubills), amounting to €6.6 billion net. State and local governments issued bonds worth €1.0 billion net.

Enterprises' capital market debt higher

Domestic enterprises issued bonds with a net value of €4.9 billion in the reporting month, compared with €0.7 billion in April. On balance, non-financial corporations were the chief issuers.

Net issuance by credit institutions

Domestic credit institutions raised their capital market debt by €4.1 billion net in May, following net redemptions of €3.2 billion in April. The outstanding volume of debt securities issued by specialised credit institutions – which include, for example, public promotional banks – went up by €1.8 billion, thereby accounting for the bulk of the increase. Further growth was also seen in the outstanding volume of mortgage Pfandbriefe (€1.3 billion), of other bank debt securities that can be structured flexibly (€0.7 billion) and of public Pfandbriefe (€0.3 billion).

Purchases of debt securities

The Bundesbank was the main buyer of bonds in May, acquiring debt securities amounting to €14.4 billion net, predominantly under the Eurosystem's asset purchase programmes. Domestic non-banks purchased debt securities worth €8.3 billion net. On balance, these purchases solely involved domestic paper issued by the private sector. Domestic credit institutions expanded their bond portfolios by €5.5 billion net, while non-resident investors disposed of domestic debt securities worth €3.6 billion net.

Equity market

Net issuance of German equities

In the reporting month, domestic enterprises placed new shares worth €1.4 billion net in the German equity market. The volume of foreign equities in the German market rose by €2.5 billion over the same period. On balance, shares were purchased chiefly by domestic non-banks (€3.0 billion), but domestic credit institutions were likewise active in the market (€1.6 billion). By contrast, foreign investors reduced their equity exposure in Germany by €0.7 billion net.

Mutual funds

Inflows to mutual funds

In May, German mutual funds recorded net inflows of €5.1 billion (April: €9.3 billion). On balance, specialised funds reserved for institutional investors were the chief beneficiaries of such inflows (€4.0 billion). Among the various asset classes, the main sellers of new shares were open-end real estate funds and equity funds (€1.6 billion and €0.8 billion, respectively). The outstanding volume of foreign mutual fund units distributed in Germany rose by €0.7 billion in the reporting month. In May, domestic non-banks purchased mutual fund shares worth €5.2 billion net. Foreign investors bought German shares for €0.6 billion net, while domestic credit institutions scaled back their fund portfolio slightly (-€0.1 billion).

▪ Balance of payments

Current account surplus down sharply

Germany's current account recorded a surplus of €2.5 billion in May 2022, down €6.4 billion on the previous month's level. Although the surplus in the goods account increased, this was outweighed by the sharp shift into a deficit for invisible current transactions, which comprise services as well as primary and secondary income.

Surplus in goods account up

In May, the surplus in the goods account grew by €1.9 billion on the month to €6.2 billion, but this was due to the rise in net goods exports in merchanting trade and the decline in net imports of non-monetary gold. In foreign trade, however, imports increased somewhat more strongly than exports.

Sharp decrease in invisible current transactions primarily due to dividend distributions

Invisible current transactions shifted from a surplus of €4.6 billion in April to a deficit of €3.7 billion in May. This was primarily attributable to the decline in net receipts in primary income by €8.3 billion to €2.2 billion, with higher dividend payments to non-residents from portfolio investment playing a key role. Furthermore, the deficit in the services account widened by €1.5 billion to €2.7 billion. Expenditure expanded more strongly than receipts, especially as travel expenditure picked up as is usual at this time of year. By contrast, the deficit in the secondary income account narrowed by €1.5 billion to €3.2 billion. Higher general government tax revenue from non-residents owing to the higher dividend payments on portfolio investments in particular contributed to this decrease.

Portfolio investment sees net capital exports

In May 2022, as in previous months, financial markets continued to be influenced by Russia's invasion of Ukraine and rising inflation rates. Germany's cross-border portfolio investment generated net capital exports of €6.5 billion (April: €11.1 billion). Domestic investors added €2.9 billion worth of securities issued by non-residents to their portfolios on balance. They purchased foreign bonds (€5.5 billion), shares (€1.5 billion) and mutual fund shares (€0.7 bil-

Deutsche Bundesbank

lion), while disposing of foreign money market paper (€4.7 billion). Non-resident investors off-loaded German securities to the tune of €3.6 billion net, selling money market paper (€7.1 billion) and shares (€0.7 billion), whilst acquiring German bonds (€3.6 billion) and mutual fund shares (€0.6 billion).

Financial derivatives

In May, transactions in financial derivatives recorded net outflows (€0.5 billion).

Direct investment sees capital outflows

Direct investment generated net capital exports of €19.7 billion in the reporting month (April: €12.8 billion). Domestic enterprises injected their affiliates abroad with direct investment funds totalling €10.9 billion, boosting their equity capital by €11.6 billion. By contrast, repayments predominated in lending to affiliates abroad (€0.7 billion). Conversely, non-resident enterprises scaled back their direct investment in Germany by €8.8 billion. Although they too augmented their equity capital (€2.0 billion), the volume of intra-group loans issued to business units in Germany from abroad fell significantly by €10.8 billion.

Net capital imports in other investment

Other statistically recorded investment – which comprises loans and trade credits (where these do not constitute direct investment), bank deposits and other investments – registered net inflows of capital amounting to €21.4 billion in May (following €26.8 billion in April). Monetary financial institutions (excluding the Bundesbank) recorded net capital imports (€18.3 billion). A decline in the net external position in other investment was also registered for enterprises and households (€8.6 billion) as well as general government (€3.7 billion). By contrast, the Bundesbank's net external claims went up by €9.2 billion. Its TARGET2 claims rose by €24.3 billion. At the same time, the Bundesbank's external liabilities also increased significantly, as non-euro area residents topped up their deposits with the Bundesbank.

Reserve assets

The Bundesbank's reserve assets grew – at transaction values – by €0.2 billion in May.

Distributional Wealth Accounts for households in Germany – results and use cases

Previously, it was not possible to describe the wealth distribution of households in Germany at the level of individual households on a quarterly basis. Now, however, the Distributional Wealth Accounts (DWA) represent a new provisional dataset that combines two data perspectives: namely, they link the Bundesbank's Panel on Household Finances (PHF) with the national accounts statistics. The DWA thus incorporate the distributional information from the household survey and simultaneously reflect the quarterly dynamics and levels of the national accounts statistics in a consistent manner.

According to the DWA, wealth inequality has declined in recent years. One reason for this is that net wealth has grown particularly strongly for households in the bottom half of the distribution of wealth, albeit from a low level. These less wealthy households have accumulated a significant volume of low-risk assets, such as deposits and insurance claims, and at the same time considerably reduced their debt. Another reason for decreasing inequality is that households in the upper mid-range of the distribution benefited noticeably from the rising value of their housing wealth. Furthermore, the DWA reveal considerable heterogeneity in the composition of households' wealth. In the less wealthy half of the distribution, this wealth consists almost exclusively of low-risk assets. By contrast, the wealth structure of more wealthy households includes a much greater volume of capital market instruments and, above all, housing and business wealth.

As housing wealth, in particular, generated a high return alongside shares, the average real return on assets from 2009 to the beginning of 2022 was significantly higher in the top half of the wealth distribution than in the bottom half. In this connection, the results also show that the yield-lowering effect of inflation is especially noticeable at the lower tail of the wealth distribution. As these households chiefly hold low-yielding assets, high inflation rates consequently lead to negative real returns on their wealth in particular.

The dataset presented here is also likely to become more relevant to monetary policy in future. Multiple studies show that heterogeneity among households can affect the transmission of monetary policy. Thus, the way in which monetary policy measures work is also likely to depend on the distribution and structure of wealth. When assessing the impact of such measures, then, it generally makes sense to bear in mind the financial differences between households. It is precisely against this backdrop that the future provision of the DWA would appear to be particularly helpful for a central bank.

Introduction

DWA link microdata with national accounts statistics

With the Distributional Wealth Accounts (DWA) for households in Germany, there now exists a new provisional dataset that merges two different sources of information by linking the data from the Bundesbank's Panel on Household Finances (PHF) with the quarterly data from the national accounts statistics. These DWA enable analyses to be carried out at the level of individual households. In concrete terms, this means that decisive statements can be made on wealth and debt developments along the wealth distribution. Since the effectiveness of monetary and economic policy measures depends, amongst other things, on the distribution and structure of wealth and any potential associated balance sheet constraints, the provision of distributional statistics such as these seems particularly helpful for central banks. The dataset is still in the development phase, but significant progress has already been made. Potential adjustments as the process continues cannot be ruled out.

Key analytical findings reveal heterogeneous developments that usually remain hidden in macrodata

This article starts by providing an overview of the process of creating the DWA for households in Germany. In addition, it analyses the development of the distribution of wealth since 2009 in a stylised form. It goes on to determine portfolio returns at the individual household level and to analyse their development over time using the DWA. Finally, economic policy conclusions are drawn. The overall findings are as follows:

– The DWA provide higher-frequency and comparatively timely data on the distribution of various assets and liabilities across households in Germany.

– According to the DWA, wealth inequality has decreased since around 2014. This is due, for one thing, to the fact that aside from building up their financial assets substantially, the bottom half of the wealth distribution reduced their debt to a significant extent, thus contributing to an increase in

net wealth. For another, the upper mid-range of the distribution benefited perceptibly from an increase in the value of housing wealth.

– The data from the DWA also indicate that there are significant differences in the composition of households' wealth along the wealth distribution. For example, the assets held by households in the bottom half of the distribution consist almost exclusively of low-risk forms of investment, such as deposits and insurance claims. By contrast, the wealth structure of more wealthy households includes a much greater volume of capital market instruments and, above all, housing and business wealth.

– The interaction between the different wealth structures and the varying returns on the individual asset types is reflected in noticeable differences in the level of the return on total assets along the wealth distribution. As housing wealth, in particular, generated a high return alongside shares, the average real return on assets from 2009 to the beginning of 2022 was significantly higher in the top half of the wealth distribution than in the bottom half.

Distributional wealth accounts for households in Germany: some stylised results

Quarterly DWA …

The DWA are characterised by the fact that they combine distributional information with the national accounts statistics in a consistent manner and make this available on a quarterly basis. Two sets of statistics are of key importance when compiling the DWA. First, the data from the Bundesbank's PHF study are considered. In this study, individual households in Germany are asked about their wealth and

their debt.[1] Second, data from the national accounts statistics are incorporated. The national accounts statistics describe the total wealth and wealth structure of the institutional sectors as a whole – i.e. also for the entire household sector in Germany. They include non-financial assets as determined by the Federal Statistical Office and the data on financial assets and liabilities compiled by the Bundesbank. However, the national accounts statistics do not allow for any statements to be made about the distribution of wealth. By contrast, the data from the PHF study provide very detailed information at the level of individual households, albeit only at intervals of around three years. In turn, the national accounts statistics predominantly record aggregate household wealth on a quarterly basis.[2]

… close the gap in wealth reporting between aggregated microdata and national accounts statistics …

Although both sets of statistics are compiled with the same aim in mind – that is, to describe the wealth situation of German households – there is a considerable gap in wealth reporting between the aggregated microdata of the PHF study (extrapolated) and the national accounts statistics (for more on this, see the adjacent chart). A key contributing factor here is the inadequate coverage of very wealthy households in the PHF study. Against this backdrop, experts from the European System of Central Banks collaborating in various expert groups have, since 2015, endeavoured to link the data from household surveys with the national accounts statistics for the household sector within a consistent analytical framework, thereby closing the data gaps (see also the box on pp. 18 ff.).[3]

… and consistently reflect dynamics and levels of the national accounts statistics

Ultimately, the provisional dataset resulting from the work of the expert groups contains valuable information from both sets of statistics: it takes into account the distributional information from the household wealth survey at the individual household level, as well as the quarterly dynamics and levels of the national accounts statistics for the period since 2009. In this context, the DWA record level data on the basis of various wealth groupings for the following types of assets and liabilities: deposits,

debt securities, listed shares, investment funds, insurance claims, financial and non-financial business wealth, housing wealth and liabilities in the form of mortgages and other debt.[4] Financial business wealth includes equity investments, i.e. unlisted shares and other equity. Non-financial business wealth, on the other hand, chiefly consists of the non-financial assets of sole proprietors such as self-employed persons and freelancers.[5] The net wealth of a household is ultimately calculated as the difference between total assets and liabilities (see also the chart on p. 21).

---

1 With its Panel on Household Finances (PHF), the Bundesbank's Research Centre is able to capture the situation of households in Germany. On average, data for around 4,000 households are available for each of the three existing survey waves of the PHF. These data make it possible to analyse a multitude of topics: income and wealth distribution, property ownership, saving behaviour and provision for old age, jobs, and family. In addition, the PHF data feed into the Household Finance and Consumption Survey, a study conducted by the Eurosystem central banks, and thus play a key role at not only the national but also the European level.
2 Data on non-financial assets are usually only available at the annual level.
3 See European Central Bank (2020).
4 Insurance claims essentially refer to voluntary pensions, as they primarily comprise life insurance and annuity entitlements. Other debt constitutes all loans other than mortgages, such as consumer loans.
5 Owing to their legal form, these sole proprietors are to be assigned to the household sector.

Methodological aspects in compiling Distributional Wealth Accounts for households in Germany

There are currently two key sets of Bundesbank statistics which provide information on the wealth situation of households in Germany. First, there is the Panel on Household Finances (PHF), which gives detailed information on the individual wealth and debt situation of the households surveyed. Second, the national accounts statistics provide aggregate information on the amount and structure of wealth of the entire household sector. As both sets of statistics focus on household wealth in Germany, it might initially be assumed that they provide similar aggregate wealth figures. However, a simplified comparison of the data from the wealth survey and the national accounts statistics reveals significant differences (see also the chart below). An expert group within the European System of Central Banks (ESCB) identified two main sets of factors that explain these differences.[1]

The first set of factors mainly concerns conceptual and methodological differences. These can potentially relate to individual or all components of wealth, and include differences in the definition of the population or periodicity and timeliness of the statis-

tics. However, differing valuation concepts between the two sets of statistics are also a decisive factor. For example, the survey data typically reflect household self-evaluations of different assets and liabilities, whereas the national accounts statistics primarily measure assets on the basis of market values. Finally, when comparing the data, it should be borne in mind that wealthy households are typically underrepresented in the realised samples of the wealth survey.

The second set of factors relates to instrument-specific differences, which are mainly due to divergent definitions. In order to take account of these conceptual differences in particular, the Distributional Wealth Accounts include only those wealth com-

---

1 In December 2015, the Expert Group on Linking Macro and Micro Data for the household sector (EG-LMM) was established within the ESCB with the aim of analysing the comparability of data from the household wealth survey and the national accounts statistics. Based on these results, the expert group which succeeded it (Expert Group on Distributional Financial Accounts) was then tasked with developing a procedure for the compilation of the Distributional Wealth Accounts.

Deutsche Bundesbank

ponents which are sufficiently comparable between the two sets of statistics. They do not, however, include those wealth positions that are only recorded in one of the two sources, such as "non-life insurance reserves", which only form part of the financial accounts. They also exclude assets which have a low degree of comparability owing to significant differences in how they are defined. These include occupational pensions, financial derivatives and other accounts receivable/payable. Ultimately, this approach results in a definition of wealth which – as measured by the national accounts statistics – covers around 90% of households' total assets.[2]

Despite using an adjusted concept of wealth, when it comes to net wealth there is still a notable gap between the aggregate of the household survey and the corresponding data from the national accounts statistics. On average, the net wealth recorded in the household survey over the three PHF waves is around €2,000 billion (20%) lower than the level in the national accounts statistics. A major contributing factor here is the absence of very wealthy households in the PHF, which continues to present a great challenge.[3] For one thing, only a small number of high-net-worth households are represented in the population. For another,

willingness to participate in surveys decreases as net wealth increases.[4]

An advanced approach was developed to close the data gap for this population group

---

2 It should be noted here that for financial business wealth (sub-component of total business wealth), the corresponding level in the financial accounts (sum of unlisted shares and other equity held) appears to be recorded only incompletely. Stylised back-of-an-envelope calculations indicate that unlisted shares and other equity issued by non-financial corporations in Germany are underreported in the financial accounts. Accordingly, the reported volume for these two instruments is likely to be around €1,250 billion too low overall. Thus, when compiling the Distributional Wealth Accounts, an appropriately corrected level in the financial accounts is used. It is estimated that around 90% of German enterprises are family-owned (see Foundation for Family Businesses (2019)). Assuming that most of the aforementioned liabilities are held by households, this would imply a correction factor of 4.8 for households' holdings in 2017 with regard to these two wealth components. To obtain a time series for the correction factor, it is also assumed that the original stock was largely recorded correctly in 1991, implying a correction factor of 1. On the basis of these two data points, a time series for the correction factor can be computed using linear interpolation/extrapolation. Finally, multiplying the raw figure from the financial accounts by this time series yields an appropriately corrected value. For more on the underreporting of aggregate business wealth, see also Albers et al. (2020).
3 See European Central Bank (2020).
4 See, for example, Westermeier and Grabka (2015). It should be noted, however, that the Socio-Economic Panel (SOEP) was able to significantly improve the data situation in this area of the net wealth distribution by means of a new additional sample (SOEP-P) concerned with high wealth (see Schröder et al. (2020)).

as much as possible. The idea behind this approach is to add the absent very wealthy households to the original household survey dataset using a "rich list".[5] The observations on net wealth from this list supplement the PHF dataset. Since these data only take into account the top tail of the net wealth distribution, synthetic wealthy households are also estimated which then supplement the original PHF dataset as well. The net wealth of these synthetic households lies between that of the members of the rich list and the wealthiest households included in the wealth survey (see also the chart on p. 19).[6]

As the data on the added wealthy households all relate to net wealth, further adjustments are needed at the level of the individual wealth components in order to close the data gaps. The bulk of the gap in liabilities is attributed to very wealthy households. This allocation is based on two assumptions: first, that very wealthy households have access to generally large-volume credit contracts; and, second, that the liabilities of comparatively less wealthy households are adequately captured in the PHF.[7] Now that data on liabilities are available alongside net wealth, the level of gross wealth can be determined. The composition of gross wealth is based on the results of an additional SOEP-P sample and the 2018 Global Family Office Report.[8] This composition is ultimately assigned to very wealthy households as an initial portfolio structure.[9] In the event that the added households now hold certain assets on a larger scale than suggested by the data gaps, further adjustments are made. In concrete terms, this means that excess holdings are spread across comparable assets which are still underreported.[10] The portfolios of the synthetic households and rich list households generated in this way thus complement the original data from the wealth survey. It is shown that simply by adding the very wealthy households that have so far been absent from the data, the underre-

porting when it comes to total net wealth can be reduced by more than 50% on average.[11] The remaining data gaps are finally closed by means of proportional allocation, whereby each household is allocated part of the remaining data gap according to its share in the instrument-specific volume re-

---

5 Specifically, data provided by "manager magazin" on the net wealth of the wealthiest Germans in 2011, 2014 and 2017 are used.
6 This is done under the assumption that the wealth of very affluent households follows a Pareto distribution. The Pareto distribution is estimated on the basis of the PHF households whose net wealth exceeds €1 million and the wealth data from the rich list. Using this estimated distribution, synthetic households which lie in the unobserved range are then randomly drawn and added with a corresponding level of net wealth. For more on the approximation of the wealth distribution using Pareto distribution in the high-wealth range, see, inter alia, Vermeulen (2018) and the sources cited therein, as well as Waltl and Chakraborty (2022).
7 Liabilities are allocated to very wealthy households proportionally to net wealth, subject to the constraint that the later structure of gross wealth essentially matches the portfolio structure of millionaires in the SOEP-P. For more on the wealth structure in the SOEP-P, see Schröder et al. (2020).
8 See Schröder et al. (2020) and UBS/Campden Research (2018).
9 According to UBS/Campden Research (2018), the following portfolio structure is assumed: deposits (7.0%), debt securities (16.2%), listed shares (28.0%), investment funds (5.7%), financial business wealth (21.6%), housing wealth (18.1%), non-financial business wealth (3.4%). Taking into account the SOEP-P data, the portfolio shares of housing wealth and total business wealth are adjusted to 20% and 60% respectively. The remaining portfolio shares are rescaled accordingly, so that the sum of all shares equals 100%. This ultimately produces an initial portfolio composition which essentially reflects the results of the SOEP-P and serves as a benchmark.
10 Thus, for example, excess holdings of debt securities are distributed equally across investment funds and insurance claims. This reflects the fact that households can invest in debt securities indirectly via investment funds and life insurance. Similarly, excess holdings of listed shares are assigned to business wealth as well as to investment funds and insurance claims. Finally, excess holdings of housing wealth are distributed among shares, business wealth, investment funds and insurance claims.
11 Given average aggregate net wealth of around €10 trillion recorded across all three existing PHF survey waves, the data gap amounts to an average of roughly €2 trillion. By adding synthetically produced households to the original data from the household survey, this gap can be closed by an average of more than 50%.

corded so far.[12] This leads to an instrument-specific increase in holdings across all households, which ultimately enables full alignment of the wealth survey with the national accounts statistics.

After linking the three existing PHF survey waves to the relevant data from the national accounts statistics, interpolation and extrapolation are used in the final step to translate the dynamics from the national accounts statistics to the individual households. The resulting dataset therefore consistently takes into account not only the distributional information from the wealth survey but also fully includes the levels and the quarterly dynamics of the national accounts statistics for the period since 2009.[13] Finally, however, it should be noted that the data at the current end, in particular, are subject to some degree of uncertainty owing to the extrapolation process. In this context, the extrapolation of the individual household

data after the last available PHF survey wave from 2017 implicitly assumes that the saving and investment behaviour of households observed up to that point has not fundamentally changed. This simplifying assumption can be problematic, as crisis situations such as the coronavirus pandemic can, in principle, permanently change households' motives for saving and thus also their saving and investment behaviour.[14]

---

12 In this context, the advantage of proportional allocation is that, at the instrument level, it does not skew the distributional information generated up to that point in any specific direction but leaves it unchanged. **13** On average, data for around 4,000 households are available for the three existing PHF surveys. In addition, there are another 3,000 very wealthy households which are artificially generated on the basis of an estimated Pareto distribution in order to correct the underreporting at the top tail of the wealth distribution. **14** See, for example, Ercolani et al. (2021).

Breakdown of household groupings along net wealth distribution …

The chart on p. 22 shows the respective level of net wealth and the share in total net wealth for different groupings of households along the net wealth distribution. Specifically, the respective aggregate net wealth of four wealth groupings is considered: the top 1% of the wealth distribution, the next 9% of the distribution (90% to 99%), the 40% after that (50% to 90%) and the bottom half of the wealth distribution (0% to 50%). The DWA for the household sector show a high level of overall wealth inequality, although this has declined slightly over the duration of the dataset (from 2009 onwards, in other words). While the top 10% of the wealth distribution held more than 50% of German households' total net wealth over the observation period, the bottom half of the wealth distribution accounted for an extremely small share, averaging 0.6%. However, the distribution has shifted slightly in favour of the bottom half of the distribution over the observation period. The share of total net wealth held by the less wealthy 50% of households

context, households in the bottom half of the distribution have accumulated a significant volume of low-risk assets, such as deposits and insurance claims, in their financial portfolio, whilst at the same time markedly reducing their liabilities. The upper mid-range of the distribution, on the other hand, has benefited comparatively strongly from the increased value of housing wealth. One reason for this is that less wealthy households rarely own real estate. Another reason is that housing wealth accounts for a much smaller share of very wealthy households' total assets. The increases in house prices observed in recent years have therefore probably tended to have a balancing effect on the net wealth distribution, taken in isolation.[8] Finally, the growth in net wealth seen in the top 1% of the distribution is mainly attributable to increases in business wealth. The high share of growth accounted for by this asset type at the top tail of the distribution also reflects the increased importance of corporate savings in the wealth development of very wealthy households in recent decades. Although these are typically retained corporate profits, they are ultimately attributable to shareholders.[9]

The divergent developments in net wealth are due, amongst other things, to unequally distributed asset types, which are reflected in discernible differences in the wealth structure along the wealth distribution. Similar differences can also be identified in the euro area and in the United States (see also the box on pp. 23 ff.). Looking at the average structure of total wealth (gross) for the four wealth groupings between 2009 and 2021, it can be seen that the financial portfolio, in particular, dominates the asset structure of the bottom half of

… accompanied by discernible differences in wealth structure

rose from 0.2% in 2009 to more than 1.2% in 2021.[6]

… reveals unequal wealth developments …

Against this backdrop, the chart on p. 25 shows average quarterly growth and the contributions to growth of major asset categories for the four different groupings of households. For the purpose of clarity, a distinction is made here between the financial portfolio, business wealth, housing wealth, and liabilities.[7] The aggregate net wealth of households in Germany has grown by an average of around 1.3% per quarter since 2009. This growth has been particularly strong for the bottom half of the distribution, albeit starting from a low level. In this

---

6 In a longer-term context, however, a rise in inequality can be seen. For example, calculated in real terms (i.e. with all assets adjusted for purchasing power), the share of total net wealth accounted for by the bottom 50% of the distribution declined from more than 5% to less than 3% in the period between 1993 and 2018, thus almost halving. For more information, see Albers et al. (2020).

7 The financial portfolio comprises deposits, debt securities, listed shares, investment funds and insurance claims.

9 See also Bauluz et al. (2022) and Mian et al. (2020).

Net wealth distribution and portfolio structure of households in Germany by international standards

We will examine below how the net wealth distribution and portfolio structure of households in Germany compare with other countries, using the euro area (including Germany) and the United States as benchmarks. The dataset for the euro area is identical to that for Germany in terms of the definition of instruments. However, at the upper tail of the distribution, only values for the top 10% are available. In the German data, the wealth groupings "top 1%" and "next 9%" are consolidated accordingly. The figures for the United States are consolidated in the same manner. In addition, the data for the United States differ, in some cases considerably, from the German and euro area-wide figures regarding the definition of instruments. As a result, the portfolio breaks down into only three larger categories, where comparability is better than in the granular analysis: housing wealth, equity and business wealth (including investment funds), and other financial assets, defined here as the difference between total assets and the other two categories. It consists, in particular, of deposits and claims on insurance corporations.

Net wealth is distributed more unevenly in Germany than in the euro area, but is less concentrated than in the United States (see the adjacent chart).[1] According to this, the percentage share of the wealthiest 10% of households at the end of 2021 was somewhat smaller in the euro area than in Germany, but was noticeably higher in the United States. The share of the next 40% in Germany is roughly as high as in the euro area, but much larger than in the United States. In Germany, the share of the less wealthy 50% of households in total net wealth was around as small as in the United States. In the euro area, however, this share is noticeably higher. The net wealth distribution in Germany has changed only slightly compared with the first quarter of 2011. In the euro area, it has shifted from the top 10% of the distribution to the next 40%. In the United States, by contrast, the next 40% surrendered wealth shares to both the top 10% and the bottom 50% of the net wealth distribution.

The distribution of various wealth components between wealth groupings varies only marginally (see the upper chart on p. 24), with almost all housing wealth split halfway between the top 10% and the next 40% of the distribution. Equity and business wealth is almost exclusively owned by the top 10% of the distribution. German households stand out by comparison in terms of the distribution of other financial assets. Almost half of these are held by those households

at the upper midpoint of the distribution. In the euro area and the United States, by contrast, the figure is just over one-third. The top 10% of the distribution in Germany hold a significantly smaller share, comparatively speaking. Liabilities, however, are distributed more evenly across the three wealth groupings. Owing to the uneven distribution of assets, this is reflected in significant differences in net wealth.

On the other hand, portfolio composition varies quite significantly across wealth groupings (see the chart below). In comparison with housing wealth, equity and business wealth are much more important in the top 10% of the distribution in the United States than in Germany and the euro area. By contrast, housing wealth plays a considerably smaller role. This means that the top 10% of wealth distribution in the United States is highly exposed to changes in corporate valuations. By comparison, their counterparts in Germany and the euro area are exposed, in particular, to house price swings. With regard to the next 40%, housing wealth, which accounts for just over two-thirds of the overall portfolio, is

Deutsche Bundesbank

significantly more important in Germany and the euro area than in the United States, where housing wealth makes up only just over one-third. By contrast, for the next 40% of the distribution in the United States, other financial assets, especially in the form of pensions, account for around one-half of total assets. In Germany and the euro area, on the other hand, the share is only just over one-quarter. The portfolios of the less wealthy 50% of households in Germany and the United States are roughly comparable, with housing wealth and other financial assets each accounting for around half of this figure. By comparison, the share of housing wealth in the euro area, at just over two-thirds, is roughly twice that of other financial assets. For the bottom half of the wealth distribution in all three regions, equity and business wealth tend to be essentially a non-factor. Overall, this wealth grouping is therefore less exposed

to market price fluctuations. However, owing to the high level of liabilities, especially those held by households in Germany, changes in interest rates can expect to be passed through much more strongly to the servicing of debt.

the wealth distribution.[10] In addition, the rate of real estate ownership is comparatively low.[11] By contrast, housing wealth makes up more than half of the total assets of the next 49%. For the top 1%, business wealth plays a significant role as well (see the upper chart on p. 26). Overall, it can be seen that the wealth of the top 1% of the distribution is therefore primarily vulnerable to changes in the valuation of business wealth, which largely consists of equity investments in the form of unlisted shares or other equity. By contrast, the wealth of households in the upper mid-range of the distribution is primarily exposed to potential price fluctuations for housing wealth.

10 The average portfolio structure is determined by working out the average across all household-specific wealth structures. When depicting averages, conditional mean values are shown throughout, unless otherwise stated. Specifically, only households with positive total (gross) assets are included in the calculation.
11 According to the DWA, the rate of real estate ownership in the top and bottom halves of the distribution stands at around 85% and 15% respectively. See also Deutsche Bundesbank (2019).

fluctuations. However, this precautionary saving motive declines as wealth rises. As a result, less liquid and thus riskier asset types are increasingly held in the portfolio.[12] Moreover, it is striking that the aggregate structure of the financial portfolio is most closely aligned with the average portfolio composition of the two top wealth groupings, i.e. the top 10% of the wealth distribution. This is essentially attributable to the size of the financial portfolio of this top 10%. The macroeconomic aggregate is primarily dominated by the financial assets held by these households: the wealthiest 10% hold around a 50% share of the aggregate financial portfolio wealth, while the less wealthy 50% hold only about 8%.

A disaggregated analysis of portfolio returns on financial assets

Possible to calculate individual returns on financial portfolio using DWA

In view of the varying structure of financial portfolios along the net wealth distribution, it is to be expected that differences in portfolio composition, coupled with differing instrument-specific returns, will produce a very mixed picture with regard to individual portfolio returns. As it is possible to calculate portfolio returns at the level of individual households over time using DWA data, these returns will be examined more closely in the following.

Significant differences evident in composition of financial portfolio, too

In addition to the varying structures of households' total assets, however, the provisional DWA also show significant differences in the composition of their financial portfolios (see the lower chart on this page). The financial portfolio of the bottom half of the distribution consists almost solely of deposits and insurance claims. By comparison, the share of securities (debt securities, listed shares and investment funds) in the financial portfolio of wealthy households is significantly higher. Households in the bottom half of the wealth distribution favour liquid assets, such as deposits, precisely so they do not need to reduce their consumption as much in the event of unexpected income

Calculation of disaggregated returns uses approach for determining aggregate total return

The methodology used to calculate disaggregated returns essentially follows the approach used to determine the aggregate total return.[13] The financial portfolio considered here comprises the following types of asset: deposits, debt securities, listed shares, investment funds and insurance claims. The total return on households' financial portfolios is calculated based on their main sources of income. Whilst interest payments are the only source of in-

Deutsche Bundesbank
come a bank deposit can generate, for other types of financial asset, such as listed shares, debt securities, investment funds and insurance claims, income flows also depend on price effects. In addition, shares and investment funds that invest in equities commonly pay out dividends, too. Any attempt to calculate households' total return on the financial portfolio therefore needs to consider not just interest payments but these other components as well. The analysis also takes into account the fact that the purchasing power of nominal returns fluctuates due to inflation. This means that all the returns are analysed in real terms.[14]

Clear differences in returns on different types of financial asset

The above chart depicts the real returns on individual asset types since 2009. Developments here have varied quite considerably over the past few years. For instance, the real return on bank deposits and debt securities has been mostly negative in recent years. By contrast, the real return on listed shares and investment funds was predominantly positive, despite occasional fluctuations. Insurance claims also recorded a positive real return, for the most part. On average, however, this was lower than the return on securities. If the instrument-specific returns are now weighted by their share of the individual financial portfolio, the total real return of a household can be calculated.

The development of portfolio returns along the distribution of wealth is shown in the chart on p. 28. The continuous lines show the mean value of the respective wealth grouping at a given point in time. The shaded area represents the range of variation between the 25th and the 75th percentiles of the respective grouping. A comparison of the four wealth groupings shows that in the period between 2009 and the first quarter of 2022, the average real return (dashed line) rose as net wealth increased.[15] While the average real return comes to a mean of 0% for the bottom 50% of the distribution, it stands at around 1.5% for the top 1%. Furthermore, it can be seen that the volatility of the returns increases as net wealth rises. This is, first and foremost, the result of higher capital market investment; although households achieve higher returns on the capital market, they simultaneously bear heightened risk in the form of fluctuating asset valuations. Additionally, the shading shows that heterogeneity within a grouping also increases as net wealth rises.

Average real return rises with increasing net wealth

14 For a detailed account of how real returns are calculated, see Deutsche Bundesbank (2015).
15 As the current DWA only provide data up to and including the fourth quarter of 2021, provisional portfolio returns for the first quarter of 2022 are calculated on the basis of the weighting from the fourth quarter of 2021.

Deutsche Bundesbank

Varying portfolio structures and differing returns on individual asset types reflected in marked differences in rate of return

Differences in the rate of return between wealth groupings are due to variations in portfolio composition coupled with the differing returns on individual asset types. This becomes particularly evident when looking at the contributions of the various assets to the total return across the four wealth groupings (see the chart on p. 29). For example, the total return for the bottom half of the wealth distribution is shaped almost exclusively by low-risk assets in the form of deposits and insurance claims. As the return on these two asset types has been relatively weak in recent years, the total return has also been correspondingly low and, in most cases, even negative. By contrast, the return for the top 10% of the wealth distribution was influenced significantly by the return on capital market instruments over the observation period. In particular, positive price developments contributed to high returns, which were then reflected correspondingly in the total return. For comparative purposes, the chart on p. 29 also tracks the development of aggregate real returns on the financial portfolio produced when only national accounts data are used for the calculation. Here, it can ultimately be established that analyses which do not take distributional information into account – such as the aggregate real portfolio returns of households in Germany[16] – have only presented a representative picture for the top end of the

wealth distribution. By contrast, basing an analysis on the DWA allows for a much more differentiated assessment.

Portfolio returns of households in Germany including housing wealth

In addition to the different structures in the financial portfolio, however, the DWA also show an unequal distribution of housing and business wealth across individual household groups: the wealth in the bottom half of the wealth distribution is predominantly made up of financial assets. By contrast, housing and business wealth account for a significant share in the top half. The focus on the financial portfolio therefore only offers an incomplete view with respect to the performance of total household assets. Taking the above into account, the following analysis additionally documents returns on total assets along the distribution. Here, disaggregated returns on assets are, as a rule, calculated using the same method as disaggregated returns on the financial portfolio. The key difference, however, is that financial

Housing and business wealth also unevenly distributed

16 For information on the development of aggregate household portfolio returns in Germany, see Deutsche Bundesbank (2021c).

and non-financial business wealth and housing wealth are now also taken into account alongside traditional financial assets:

– Financial business wealth: this item comprises equity investments that are not traded on organised markets. Owing to a lack of market data, it is not possible to directly calculate the return for these instruments. It is therefore assumed that returns are generally similar to those of comparable tradable instruments. In the case of unlisted shares, for example, the same valuation changes and dividend yields are recognised as for listed shares.[17] The sum of these two components gives the total return on unlisted shares. Changes in the valuation of other equity are approximated on the basis of the information provided in the financial accounts.[18] The portion of the returns attributable to profit distributions is assumed to be equal to the observed dividend yield on listed shares. As with unlisted shares, these two components result in the total return on other equity. Finally, a weighted average is calculated from the two returns. This value is derived from the levels in the financial accounts for unlisted shares and other equity. This ultimately reflects the total return on financial business wealth.

– Non-financial business wealth: it is not possible to directly determine the return here either. However, this type of asset is, in principle, very similar to other equity.[19] For this reason, performance is estimated for non-financial business wealth in the same manner as for other equity.

17 In this context and in the absence of more detailed information, an identical sectoral structure is implicitly assumed for listed and unlisted public limited companies.
18 The valuation change is the difference between the quarterly stock change and the corresponding transaction.
19 If, for example, an individually-owned enterprise were to change its legal form to that of a general or limited partnership, the enterprise would typically be assigned to the non-financial corporations sector. The owner household would then hold a corresponding amount of other equity instead of the non-financial business wealth.

Deutsche Bundesbank
– Housing wealth: this category includes both dwellings and the land underlying dwellings. Returns are calculated using the house price and rent price indices of the Federal Statistical Office by applying a rent-price approach.[20] The year-on-year change in the house price index corresponds to the change in the valuation of housing wealth. The change in the rent price index compared with the previous year's figure for the house price index gives the rental yield. The total return on housing wealth is then calculated using the valuation changes and the rental yield.

Housing wealth in particular posted high returns in the 2009 to Q1 2022 period alongside shares

The above chart depicts the real returns on the three asset types since 2009. Over time, they have developed quite differently. Real returns on housing were consistently positive, rising from just over 3% in 2009 to around 11% at the beginning of 2022. By comparison, real returns on financial and non-financial business wealth were more volatile and also, on average, lower. They were even clearly in negative territory during the financial and economic crisis and the European sovereign debt crisis.

Taking these three additional asset types into account, it is now possible to calculate a real return on total assets which is expanded to include these asset components. The chart on

p. 31 shows the development of real returns on the financial portfolio and on total assets along the wealth distribution. The lines show the average real returns for the respective wealth grouping. This expanded perspective on the real return on assets reveals clear differences: compared with the real return on the financial portfolio, the real return on assets is noticeably higher, especially for households in the top half of the distribution of wealth.

Taking housing and business wealth into account, real return on assets is noticeably higher, especially for the top half of the wealth distribution

The main reason for these differences is the low level of housing and non-financial wealth in the bottom half of the wealth distribution when compared with the top half. Around 90% of households' real return on assets in the 50% to 99% range of the distribution was based on contributions from housing wealth (see the chart on p. 32). As this type of asset (alongside shares) recorded, on average, the highest return of all asset components in the observation period, it played a key role in

A low level of housing and non-financial wealth gives rise to a comparatively low real return on assets in the less wealthy half of the distribution

---

20 In principle, both indices only reflect their own dynamics. However, the rental yield corresponds to the development of rents in relation to the value of the real estate. Consequently, this approach initially envisages scaling the two indices according to an initial rent-price ratio at the starting time t_0 (see Jordà et al. (2019)). Based on this initial value, both indices can be depicted at each time t in such a way that the ratio of the scaled indices reflects the development of the rent-price ratio over time. The initial value is taken from the Jordà-Schularick-Taylor Macrohistory Database (version: 5 March 2021) (see Jordà et al. (2017)).

Deutsche Bundesbank
achieving a high total return. Housing wealth also made a significant contribution to total returns for the top 1% of the wealth distribution. This was, however, additionally boosted by a distinct contribution from business wealth. Overall, the contribution of the financial portfolio to returns plays only a minor role for households in the top half of the wealth distribution. By comparison, while housing wealth also made a consistently positive contribution to returns for the bottom half, this was nevertheless comparatively small, owing to the low proportion of housing wealth in the total. In addition, the results as a whole show that, in real terms, the yield-lowering effect of inflation is particularly noticeable at the bottom end of the wealth distribution. Compared with the rest of the households, the total assets of these households consist mainly of low-interest deposits. In this respect, high inflation rates tend to lead to negative real returns on assets.[21]

Households in the bottom half of the distribution nevertheless recorded a marked easing effect from a considerable decline in real interest expenditure

However, the finding that there is a comparatively low real return on assets for the bottom half of the wealth distribution owing to the high importance of low-yielding assets in the asset structure disregards the fact that the low interest rate environment of recent years also had a noticeable impact on the real interest rate on liabilities. Last year, for example, the real interest burden for mortgages and other

debt reached historical lows of around -2.7% on average. By comparison, this figure stood at just over 5% in 2009. In order to account for this easing effect, the real return on a household's assets is additionally adjusted for real interest expenditure. The average leverage ratio (total liabilities as a percentage of total assets) of the bottom 50% of the distribution stood at around 90% in the observation period; in the top half, this ratio was only slightly more than 10%. As it is particularly those households in the bottom half of the distribution of wealth that are relatively heavily indebted, the adjustment has a notable effect in this area above others. For example, the adjusted real return on assets for the bottom half is clearly shifted into negative territory (see the upper chart on p. 33). However, this return has recorded a discernible upward trend over the past few years owing to the increased easing effect. It must nevertheless also be noted that around 20% of all households in Germany, which are located

---

21 It should be noted here that according to the consumer price index, the inflation rate is assumed to be identical for all households at time t. This is, however, a simplifying assumption, as it can mask considerable heterogeneity among households. Studies show, for example, that households with lower incomes are exposed to significantly higher individual inflation rates than households with higher incomes. See Gürer and Weichenrieder (2020). As this aspect would, in principle, reinforce the above assessment, this does not affect the general statement based on the available results.

almost exclusively in the bottom half of the distribution of wealth, currently hold low-yielding assets for the most part while, at the same time, having no debt. These households therefore cannot benefit from lower real lending rates. This is why the current high level of inflation is mainly weighing on these households' low level of wealth in the form of significantly negative real returns on assets.

■ Conclusion

The Distributional Wealth Accounts (DWA) for households in Germany represent a new provisional dataset combining two data perspectives: namely, they link the Bundesbank's Panel on Household Finances (PHF) with the national accounts statistics. The DWA incorporate the distributional information from the PHF and simultaneously reflect the quarterly dynamics and levels of the national accounts statistics in a consistent manner. As the dynamics of the dataset are derived from the national accounts data, the DWA also have a distinct advantage in terms of temporal availability compared with the complex and time-consuming PHF. This ultimately allows comprehensive analyses to be carried out on a quarterly basis at the level of individual households. Statements can then be made regarding the development of the wealth and debt situation along the wealth distribution, for example. According to these statements, the DWA show that wealth inequality has decreased slightly in recent years. This is due, on the one hand, to the fact that growth in net wealth for the bottom 50% of the distribution was particularly steep – albeit starting from a low level. In this context, the households in the less wealthy half built up a significant volume of low-risk assets such as deposits and insurance claims, whilst at the same time markedly reducing their debt. On the other hand, households in the upper mid-range of the distribution benefited noticeably from the rising value of their housing wealth.

DWA consistently reflect data from the PHF and the national accounts statistics

DWA reveal heterogeneity among households which is typically hidden in macrodata

The DWA also reveal considerable heterogeneity among household wealth structures, which typically remains hidden when using macrodata. This aspect became particularly clear when looking at household-specific returns along the wealth distribution. Discernible differences in the composition of assets have a marked impact on the real return on assets of the respective household portfolio. For example, the wealth of the bottom half of the wealth distribution consists predominantly of low-risk asset types. The interest on these instruments has been relatively low in recent years, which has been reflected in a low total return. By contrast, households' wealth in the top half of the distribution consists to a much greater degree of capital market instruments and housing and business wealth, with these last two in particular accounting for a significant share of total wealth. As, on average, housing wealth – alongside listed shares – recorded the highest real return of all asset components in the observation period (2009 to early 2022), households in the top half of the distribution achieved a significantly higher total return. In addition, business wealth made a distinct contribution for the top 1% of the wealth distribution. Moreover, the results show that the yield-lowering effect of inflation is particularly noticeable at the bottom end of the wealth distribution. The total wealth of these

households consists largely of low-interest deposits. As a result, high inflation rates are more likely to lead to negative real returns on assets in these cases especially.

The distribution of pandemic-related savings of households in Germany

The saving and investment behaviour of households in Germany has been decisively shaped by the course of the coronavirus pandemic so far. At the start of the pandemic, for example, there was an exceptional increase in saving.[1] The main reason for this was reduced opportunities for consumption owing to measures to contain the coronavirus pandemic – businesses being ordered to close, for instance, and travel restrictions. However, concerns about catching the virus also led people to limit their spending, so this also contributed to increased saving. By contrast, precautionary saving due to expected income losses played only a minor role in view of extensive government support.[2]

In this context, the adjacent chart illustrates the exceptional increase in household saving at the beginning of 2020, as well as providing insight into how those savings were used. It shows that, at the start of the pandemic, the rise in savings was initially accompanied by large inflows to currency holdings and deposits, in particular. At the same time, there was a persistent upward trend in inflows to listed shares and investment funds. The build-up of deposits has subsided somewhat since the second quarter of 2021, which may indicate that, besides consumption normalising as some pandemic containment measures were rolled back, the additional savings were also reduced in some cases in order to cover higher energy and living costs. Given the continued strong inflows into listed shares and investment funds, the rebalancing of portfolios away from deposits and towards those specific forms of investment probably also played a certain role. Overall, the additional savings accumulated due to the pandemic are likely to have amounted to around €200 billion at the end of 2021. They are held primarily in the form of currency and deposits as well as listed shares and investment fund shares.[3]

Given the high level of additional savings observed at the aggregate level, the question arises as to how these are distributed across individual households. This aspect can be illustrated in a stylised way using the Distributional Wealth Accounts. To do so, a counter-

Deutsche Bundesbank

---

1 This phenomenon can also be observed in other advanced economies. See European Central Bank (2021a).
2 See Deutsche Bundesbank (2021b, 2022) for savings motives in connection with the pandemic.
3 The volume of additional savings is determined by comparing quarterly saving since 2020 with the average quarterly savings for 2018 and 2019 (for a similar approach, see Batty et al. (2021)). The cumulative deviations over the 2020 to 2021 period ultimately yield the total volume of additional savings accumulated. According to this approach, the cumulative additional savings amount to around €200 billion. Calculations based on the macroeconomic projections point to comparable figures (see Deutsche Bundesbank (2021b, 2022)). The use of the additional savings can also be calculated in a similar way: the cumulative quarterly deviations of instrument-specific transactions since 2020 from the quarterly average for 2018 and 2019 indicate how the additional savings were invested during the observation period.

factual version of the Distributional Wealth Accounts is prepared, which assumes that there were no additional savings due to the pandemic.[4] Comparing the holdings in the counterfactual Distributional Wealth Accounts at the end of 2021 with the actual data ultimately reveals the distribution of the cumulative additional savings (see the adjacent chart). It can be seen that mainly households at the top tail of the wealth distribution have accumulated significant additional savings in absolute amounts. Whilst a household in the bottom half of the distribution currently has additional savings totalling around €420, a household in the top 1% of the distribution accounts for an additional amount of roughly €120,000 on average. Currency and deposits make up around 75% of the total additional savings for the bottom half of the wealth distribution. As net wealth increases, this share shifts markedly towards listed shares and investment funds.[5] In light of the significant rise in energy costs and the cost of living, the results suggest that the additional savings generally help mitigate the resulting financial burdens to a certain extent,[6] but they also show that this does not apply equally to all households. Extensive savings were built up mainly by wealthy households. Owing to the comparatively low volumes per household in the less wealthy half of the distribution, the buffer effect of the additional savings appears to be fairly limited for those households. Rising energy costs and the cost of living are therefore likely to place a greater strain on households at the bottom end of the wealth distribution compared with others.

---

4 As the aggregate transactions in the chart on p. 34 indicate that the bulk of the excess savings have flowed into currency holdings and deposits as well as into listed shares and investment funds, for the counterfactual alternative, quarterly excess savings are accordingly deducted from these two asset types (distributed proportionally across these two categories; see also Batty et al. (2021)).
5 For more on the distribution of additional savings due to the pandemic in the international context, see European Central Bank (2021a). Overall, it can be seen that households with high incomes and wealth, in particular, have accumulated additional savings (see, inter alia, Bank of England (2020), Batty et al. (2021), Deutsche Bundesbank (2021b) and European Central Bank (2021b, 2022a)).
6 See European Central Bank (2022b).

As wealth distribution can affect the transmission of monetary policy, it seems helpful to be able to take due account of the financial differences between households

In addition to the use cases outlined above (see also the box on pp. 34 ff.), the dataset presented here is likely to become more relevant for monetary policy in future. There are a great many studies focusing on the interplay between monetary policy and inequality.[22] They show that, although monetary policy measures can generally have an impact on the distribution of wealth, the development of inequality over the past few decades has been driven predominantly by factors outside the scope of monetary policy. Of course, this must be seen in light of the fact that monetary policy typically has neither the mandate nor the appropriate instruments to steer distributions in a targeted manner. It is instead the finding that heterogeneity between households can affect the transmission of monetary policy that appears much more important. This means that the effectiveness of monetary policy measures depends, amongst other things, on the distribution and structure of wealth. Balance sheet constraints could also affect the impact of monetary policy measures.[23] When assessing the impact of such measures, then, it may generally be helpful to bear in mind the financial differences between households. It is precisely against this backdrop that the future provision of the DWA seems of particular interest to a central bank.

Factors influencing international portfolio flows

The free movement of capital is a core element of open economies. It allows for efficiency gains and can help to mitigate country-specific risks internationally. Being closely interconnected with other countries can also be a source of risk, however, especially if it leads to unilateral dependencies.

Cross-border portfolio investment – transactions in equities, mutual fund shares and debt securities between residents and non-residents – accounts for a significant proportion of international capital flows. The comparatively high volatility of these transactions presents challenges in terms of economic policy, particularly for emerging market economies, but also for advanced economies, too. For this reason, there is great interest in gaining a better understanding of the factors that drive portfolio flows.

The economic literature makes a distinction between international "push" factors and country-specific "pull" factors. Domestic and foreign economic developments play a prominent role in this regard, while movements in equity markets, uncertainty, commodity prices, and the international interest rate environment are also significant drivers.

The international interest rate environment is shaped to a large extent by US monetary policy. Analysis reveals that the US Federal Reserve exerts an influence on international portfolio flows not only via "pure policy" responses, but also by means of the information that it provides on the US economy as a key driver of global economic activity. Bundesbank estimates find that monetary policy responses by the US Federal Reserve have a stronger impact on flows into bond funds investing in emerging market economies than on funds investing in advanced economies.

Another Bundesbank study shows that there is variation over time in the degree to which the drivers of cross-border capital flows affect fund flows into individual countries. In this context, there is variation across regions (advanced economies versus emerging market economies) and also across asset classes (equities versus bonds), with the international drivers of portfolio flows gaining in significance in various advanced economies, especially Member States of the European Union, over the 15 years under review. As regards portfolio flows into emerging market economies, the results are found to vary widely across countries.

Introduction

Cross-border capital flows have positive impact on economic developments, but also involve risks

The increasing interconnectedness of the global economy is directly linked to cross-border capital flows. The ability to invest capital around the world or raise capital abroad broadens the spectrum of investment opportunities. This can foster and entrench economic growth in the economies involved. However, a high degree of capital mobility is also a source of risk. Under the right conditions, it can promote abrupt swings in financial flows, destabilising the real economy.

Portfolio flows are particularly volatile

This holds particularly true for assets that are highly liquid and thereby exposed to constant influence from foreign and domestic factors. These mainly include securities that are traded globally. In the balance of payments, these cross-border securities transactions are consolidated under the item "portfolio investment". They include trading in equities, mutual fund shares and debt securities with non-residents.[1] The comparatively high volatility of these transactions presents challenges for emerging market economies in particular, but also for advanced economies, too. From an economic perspective, there is particular interest in understanding the factors that drive portfolio flows. The analyses presented in this article investigate the determinants and their significance for portfolio flows.[2] Particular attention is paid to the role played by US monetary policy as well as how the importance of international and country-specific factors varies over time.

This article begins by discussing the economic significance of cross-border capital flows, making a distinction between characteristics that support economic activity and those that inhibit it. It then explains how portfolio flows fit into the bigger picture of cross-border capital flows and the wider balance of payments, distinguishing between the various analytical methods that can be used to investigate portfolio flows. It is important to make this distinction because, in some cases, different research approaches in the economic literature come to different conclusions regarding the significance of individual factors. As there is such a wide range of factors that influence portfolio flows, this article focuses on some of the main drivers – such as economic developments, movements in equity markets, and risk aversion. Two analyses are presented in this context to highlight the effects of US monetary policy on portfolio flows as well as how the significance of drivers varies over time.

Economic significance of cross-border capital flows

Characteristics that support and stabilise the economy

Free movement of capital promises efficiency gains …

The free movement of capital, which opens up the possibility of employing funds worldwide, fosters the efficient allocation of capital around the world. As a result, consistent with the economic rationale of maximising profits and utility, financial resources are allocated where – for a given level of risk – they generate the highest return.

… and facilitates the sharing of risk …

Cross-border portfolio investment in particular offers investors a way of reducing their risk by adding a broadly diversified basket of different securities from different countries to their portfolio rather than a single paper.

… as well as a smoothing of consumption

Besides offering benefits in terms of efficiency, international capital flows are a means of offsetting temporary country-specific fluctuations in income and thus smoothing consumption.[3] Expected lifetime income and consumption projected on that basis are often disrupted by

---

1 The balance of payments statistics differentiate between portfolio investment and direct investment by categorising the former as holdings of less than 10% of an enterprise's shares.
2 See Deutsche Bundesbank (2020a).
3 The lifetime income theory posits that households prefer a smooth path of consumption to large fluctuations in their standard of living. See, for example, Obstfeld and Rogoff (1996).

unexpected events.[4] If, for example, a natural disaster depresses a country's economic output and thus also household incomes, international capital flows can help to sustain consumption through the crisis by borrowing from abroad.[5] In such a case, the households or general government affected by the natural disaster stabilise their consumption by means of an "intertemporal trade" – they borrow to bring some of their future consumption forward to the present.[6]

Characteristics that inhibit and destabilise the economy

Sudden stops, especially in emerging market economies

Having large stocks of assets or extensive liabilities abroad also entails being exposed to particular risks, however. Expectations that an economy will develop favourably typically generate strong capital imports and thus drive up that country's external liabilities. If these forecasts turn out to have been overly optimistic, financial flows can suddenly stop or, in unfavourable circumstances, even reverse. Sudden stops like this often lead to severe economic crises. One such event was the Asian crisis triggered in 1997: in the early 1990s, many South-East Asian economies were attracting strong flows from abroad. Investors seemed to have been expecting a high return on their capital in these countries. However, when the assessments of these countries' economic prospects changed, they pulled their capital out again. This process triggered severe recessions and currency crises in many South-East Asian countries. These then rippled to other parts of the world and caused crises there, too, such as in Mexico and Russia.

Advanced economies at risk of contagion as well

However, this does not mean that advanced economies are immune to financial distress and contagion, as proved in 2008 during the global financial crisis and shortly afterwards during the European sovereign debt crisis. Even countries with high net capital exports and corresponding levels of net external assets can be af-

fected, especially if those assets are insufficiently diversified.

Portfolio flows as part of the balance of payments

Importance of capital flows for an economy can be derived from balance of payments

The importance of cross-border capital flows, and thus also of portfolio flows, for an economy differs from one country to the next and can be derived from the balance of payments. The balance of payments records all economic transactions between residents and non-residents within a given period (month, quarter or year).[7] As these transactions can differ in character, they are broken down into sub-accounts: the current account, capital account and financial account.[8] Of these, the current and financial accounts are generally considered the most important. The current account records cross-border trade in goods, services as well as primary and secondary income. If this account is in surplus, this implies that a country's receipts from current transactions with non-residents are higher than the corresponding expenditure paid to non-residents. The payments associated with current transactions are recorded in the financial account.

---

4 A positive event would be an unexpected discovery of natural resources, for example, while a negative one would be an unforeseen natural disaster. For this model, the key aspect is that the event comes as a surprise. This is because a foreseeable decline in income, such as due to retirement, is, according to the lifetime income theory, generally always factored into consumption decisions, while only an unexpected change leads to an immediate shift in households' consumption and saving behaviour.
5 See Obstfeld and Rogoff (1996). The intertemporal approach to the current account is based on (net) capital flows in general. Many of the transactions belonging to this category would, in practice, be categorised as "other investment".
6 Enterprises and government, too, would generally borrow more in this kind of situation, albeit with different intentions in mind. These agents do not play any role in the intertemporal approach to the current account, however.
7 A detailed account of Germany's balance of payments for 2021 was presented in Deutsche Bundesbank (2022).
8 The current (sixth) edition of the International Monetary Fund's Balance of Payments and International Investment Position Manual states how individual transactions should be recorded.

Financial account

€ billion

Deutsche Bundesbank

averaging 4.7% of German GDP each year. Non-residents, meanwhile, have added German securities to their portfolios for an average of 2.7% of German GDP. Added up over a little more than 20 years, the figures show that portfolio flows in Germany are highly important for the national economy and that there is significance in both their stabilising and destabilising characteristics. The same holds true for other countries.

Different analytical options for portfolio flows

The body of literature on the drivers of portfolio flows has grown rapidly over the past few years.[9] However, different investigations do not always produce the same findings. This is partly because, on closer inspection, the studies differ fairly substantially in some cases.

Broad body of literature on portfolio flows, but findings are heterogeneous

First, not all studies focus exclusively on portfolio flows. Some examine international capital flows as a whole. Second, some studies break these flows down into direct investment, portfolio investment and other investment.[10] Within these categories, flows can also be subdivided further still – into equities, bonds and mutual fund shares in the portfolio investment category, for example. Equities and bonds are subject to different levels of demand, depending on the macroeconomic environment for individual investors. As a result, different study findings are possible in this regard, too, along different dimensions. It is therefore essential to define the capital and portfolio flows precisely in order to make the findings comparable.

Not all studies on international capital flows focus on portfolio flows

However, the financial account records not only payments related to current transactions, but also cross-border transactions involving financial instruments of all kinds. These also include the portfolio investment mentioned above. In addition, the financial account makes a further distinction between direct investment, financial derivatives, reserve assets, and other investment. Other investment comprises loans and trade credits (where these do not constitute direct investment) as well as bank deposits and other capital.

Flows also particularly important in relation to GDP

The analysis presented in this article centres on portfolio investment, as this is influenced in a unique way by the short-term investment decisions of international investors. The significance of this asset category for a national economy becomes clear when the individual flows are expressed in relation to gross domestic product (GDP). For example, since the introduction of the euro, German investors have purchased foreign securities for an amount

However, even investigations that focus explicitly on portfolio investment, and perhaps make a distinction between equities and debt securities as well, will not necessarily be based on the same data. While some authors take an

Most studies examine only one side of the balance of payments

---

9 See Koepke (2019).
10 See, inter alia, Barrot and Serven (2018) and Cerutti et al. (2019).

interest in the evolution of net flows, the majority of cross-country analyses use gross flows. These studies typically investigate which factors drive increased demand for or sales of a particular country's equities and debt securities in international capital markets. Applied on a global scale, this approach explains cross-border portfolio investment in its entirety.

Fund flows can be a useful proxy

Another way to investigate rising or falling demand for securities using volume data (rather than price data) is to analyse flows into funds that invest in certain countries. Investment funds pool together the financial resources of international investors and are obliged to allocate them in line with their investment strategy. The data obtained in this manner differ from balance of payments statistics in two ways. First, the funds in question also receive flows from residents, for example from German savers who acquire stakes in German enterprises in this way. Second, the data capture only securities that are traded indirectly via investment companies, but not investors' direct transactions in individual equities or debt securities. One benefit of fund data, however, is that, unlike balance of payments statistics, they are available for many countries in near real-time and at a high frequency.

Financial flows often normalised

Ultimately, cross-country studies need to make the capital flows of differently sized countries comparable with one another, which is why the original data from the balance of payments are often expressed in relation to a country's GDP. Where fund flows are used as the dataset, it makes sense to use the existing total fund volume at the start of given a period as a point of reference. This also has the advantage of largely eliminating the influence of valuation changes. Lastly, it is also possible to logarithmise the original data as a way of visualising percentage changes rather than absolute variables.

Study samples differ, too

One final point is that studies often differ in terms of frequency, observation period, or the group of countries under review. All of these

Germany's external position

€ billion

Deutsche Bundesbank
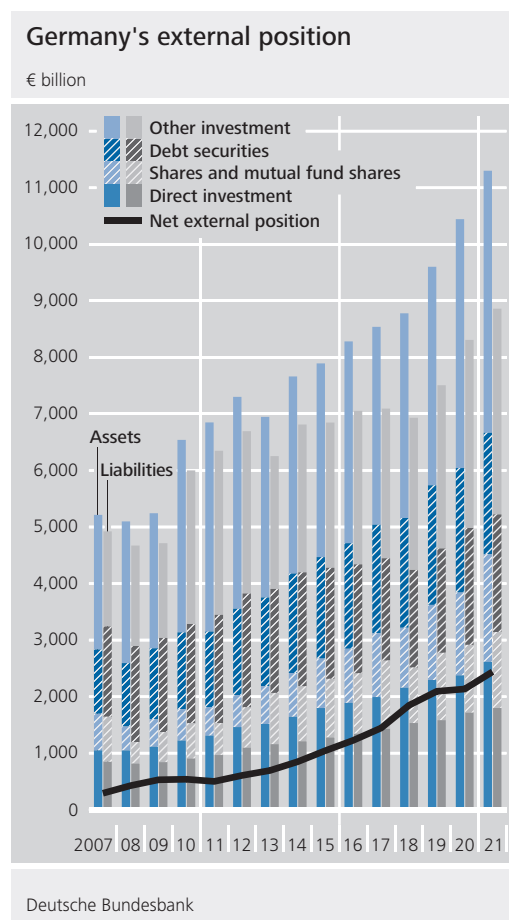

aspects mean that the empirical evidence regarding the significance of individual drivers of portfolio flows is inconsistent across studies.[11]

Selected determinants of international portfolio flows

For the most part, the economic literature already divides the drivers of portfolio flows into separate categories at a higher level, breaking them down into international "push" factors and country-specific "pull" factors.[12] According

Drivers can be broken down into international "push" factors and country-specific "pull" factors

11 See, inter alia, Bettendorf and Karadimitropoulou (2022), Fratzscher (2012) and Lo Duca (2012).
12 This categorisation goes back in particular to the work of Calvo et al. (1993). The authors found empirical evidence that international variables were especially significant as drivers of Latin American fund flows. Since then, the categorisation of drivers into push and pull factors has been used in many studies. This approach is not above criticism, however. This strict differentiation means that certain causes of portfolio flows, such as spillover effects between two countries, are not captured (see Koepke (2019) and Deutsche Bundesbank (2020a)).

to this approach, push factors lead to simultaneous and unidirectional changes in fund flows into different countries, while pull factors relate solely to fund flows into the country in question.[13]

Differentiation challenging in practice

However, in some ways, push and pull factors have a very close economic relationship with one another. It is therefore possible for one and the same variable to act as a push factor from a global perspective and as a pull factor from a country-specific perspective. An example of this is economic activity. While global economic activity is clearly a push factor, national economic activity represents a pull factor. The two factors are related, however: economic developments in large countries such as China or the United States have a significant impact on global economic activity as well. Conversely, economic activity in small open economies is crucially dependent on global economic activity. Analytically, it is thus all but impossible to draw a clear line between these two factors.

Push and pull factors can affect portfolio flows simultaneously and unidirectionally

Certain push and pull factors may indeed influence portfolio flows in the same direction. This is because domestic and foreign investments are not necessarily in competition with each other. Instead, investors first decide whether they want to invest at all and then have the opportunity to diversify their investments across borders depending on their strategy and the economic environment. As a result, unidirectional movements in push and pull factors can lead to unidirectional changes in fund flows domestically and abroad.

Economic developments an important determinant

Both global and country-specific economic developments influence fund flows into individual countries. From a macroeconomic perspective, strong economic growth increases expected returns and reduces investment risks; it therefore also leads to higher investment activity. The contribution of global economic growth increases with the strength of international trade and financial market linkages. Various empirical studies provide indications that growth in the global economy acts as a push factor.[14] However, the evidence on this matter is mixed. The relationship between the development of the global economy and capital flows appears to depend on how the respective model is specified and the region under consideration. Other studies find no statistically significant correlation whatsoever.[15] What is clearer is the significance of country-specific economic developments as a pull factor – it is clearly positive, so it supports capital flows into a country.[16] Nevertheless, the correlation is less significant in studies with high frequency data on portfolio flows.[17]

Developments in equity markets reflect expectations of future profits

In addition to current economic developments, expectations regarding the future path of the economy also play an important role in portfolio flows. Equity markets are a good proxy for these expectations because firms' equity prices are influenced by their discounted expected earnings. Accordingly, rising equity prices can be interpreted as an indication that market participants have positive expectations, while falling equity prices are typically associated with negative expectations. Economically speaking, this means that capital flows into individual countries should be positively correlated with how prices evolve in the local equity market (pull factor). However, global sentiment in equity markets is also likely to generally increase the propensity to invest in this form of investment and thus push up demand for equi-

13 On this point, Koepke (2019) also identifies a link to portfolio theory according to Markowitz (1952).
14 Some studies refer only to economic growth in advanced economies. This accounts for the bulk of global economic growth in statistical terms, however.
15 See, for example, Baek (2006), Bettendorf and Karadimitropoulou (2022) and De Vita and Kyaw (2008).
16 International trade and financial market linkages mean that, in practice, global and country-specific economic growth are often strongly correlated. In order to determine the significance of country-specific economic growth for fund flows, this first needs to be adjusted for the global economic component using statistical methods. In doing so, different estimation approaches may yield different results.
17 See, for example, Bettendorf and Karadimitropoulou (2022) and Koepke (2018).

ties in all countries (push factor).[18] Empirical studies find statistically significant evidence of correlations between equity market movements and fund flows, though it is mainly studies based on relatively high frequency data that are able to demonstrate the existence of strong correlations here.[19] This is plausible insofar as equity market movements, unlike economic data, can be mapped at a very high frequency, which gives them potentially greater short-term significance for investors.

There are risk indicators … An increased perception of risk can, for example, be caused by economic and financial crises or political disputes. Here, a distinction should be made between global risks and country-specific risks. Given the particular importance of the United States for global financial conditions, US risk indicators are often used as a proxy for global risk assessment in the financial markets.[20]

… for global risks … Uncertainty in the financial markets is typically reflected in increased volatility of equity returns. The degree of uncertainty can, for example, be derived from option prices and depicted using volatility indices such as the CBOE Volatility Index (VIX) for the S&P 500 stock index.[21] Furthermore, yield spreads have become established in the literature as a measure of risk. Well-known indicators of global risk include the TED spread (spread between the three-month LIBOR and three-month Treasury bills) and Moody's Baa-Aaa spread (spread between US corporate bonds with the corresponding ratings). While the TED spread serves as an indicator of risks in the interbank market, the Baa-Aaa spread represents risks across the entire corporate sector.

… and country-specific risks Country-specific risks can be derived in an analogous manner, for example from national measures of volatility. In periods of heightened uncertainty, investors tend to sell off the affected portfolio investments. Accordingly, portfolio investment outflows are to be expected if the perception of risk increases. Where securitised credit default swaps (CDS) are available,

their prices may also provide an indication of specific risks.

The empirical evidence lends weight to this hypothesis. A rise in the global risk assessment – expressed as changes in the VIX – is negatively correlated with the global flows to investment funds and is therefore a significant push factor. At the same time, such a rise is typically accompanied by increased demand for securities from the United States or other countries that are deemed to be comparatively safe (safe haven flows). As the VIX is derived from the US equity market, it is not surprising that its effects appear to play a particular role in equity transactions in advanced economies. In addition, evidence for alternative risk measures such as the TED spread and the Baa-Aaa spread can be found in studies analysing portfolio flows around the time of the global financial crisis. These studies show that increased demand for US securities can be observed even in cases where a global crisis originated in the United States.[22]

Uncertainty triggers shifts to comparatively safe investments

Portfolio flows are also influenced by country-specific measures of risk. Empirical studies show that external debt, the quality of political and financial institutions, and the assessments of rating agencies play a significant role as pull factors.[23] An increase in country-specific risk thus impedes further capital inflows while boosting capital outflows.

---

18 In the case of investment funds, this would be immediately evident from an increase in flows into equity funds. For balance of payments statistics, this would translate into an increase in cross-border purchases by non-banks, possibly supported by an increase in issuance.
19 See Bettendorf and Karadimitropoulou (2022), Chuhan et al. (1998), Fratzscher (2012), Froot et al. (2001) or Lo Duca (2012).
20 This relationship is discussed in the literature under the concept of the "global financial cycle". See Rey (2013).
21 The term "risk" is also used below as a synonym for "uncertainty". Here it does not mean risk in terms of the specific probability of losing capital (value at risk), but rather the intensity of price fluctuations in the equity markets.
22 See, inter alia, Bettendorf and Karadimitropoulou (2022), Fratzscher (2012) and Lo Duca (2012).
23 See Fratzscher (2012), Kim and Wu (2008) and World Bank (1997).

Rising commodity prices are a significant cost factor …

Another significant driver of portfolio flows are commodity prices.[24] They are a key cost factor, especially in the production of goods. While enterprises' dependence on commodity prices varies considerably across countries and sectors, increases in commodity prices nevertheless lead to higher costs and thus reduce enterprises' competitiveness and profits – except in the case of commodity exporters. As a result, it becomes less lucrative to finance production projects of the affected enterprises or to invest in these firms. In such an economic environment, it is to be expected that investors would offload portfolio investments, especially ones involving commodity-intensive production.

… but benefit commodity exporters

Empirical studies show that this relationship can be demonstrated across different estimation approaches. However, this driver does not act in the same direction for all countries. This is because commodity exporters tend to benefit from rising commodity prices, as price increases have a positive impact on earnings. Here, results indicate that the relationship has a greater impact on advanced economies.[25] This effect can be seen especially in relation to commodity cycles and has, for example, also been discussed in the economic policy debate on global imbalances.[26]

Impact of US monetary policy on international portfolio flows

International interest rate environment impacts portfolio flows

Portfolio flows in advanced economies and emerging market economies are strongly influenced by the international interest rate environment. As interest rates are an important monetary policy instrument, the role of monetary policy will be examined in more detail here. The focus is on monetary policy in the United States, as it significantly impacts financial conditions around the world.[27]

One possible transmission channel is through investors' search for yield and appetite for risk. A tightening of monetary policy in the United

States leads directly to higher yields on US debt securities. Moreover, it typically reduces investors' risk appetite, as a given yield target can then be achieved with a less risky investment instrument (e.g. government bonds versus equities or US equities versus emerging market equities).[28] Owing to higher interest rates, on the one hand, and investors' lower risk appetite, on the other, investments in US securities therefore become more attractive, leading to portfolio shifts at the global level.

Interest rate environment shaped by monetary policy in the United States

Empirical analyses confirm the effects of monetary policy on portfolio flows. They indicate that the Federal Reserve's monetary policy affects fund flows both in advanced economies and emerging market economies.[29] In this context, even the mere expectations of a monetary policy measure have a significant impact.[30]

Empirical analyses show the impact of US monetary policy on portfolio flows

In addition to the pure monetary policy impulse itself, the central bank can also send an information signal in press releases or press conferences by disclosing assessments of economic developments that represent new, surprising information for investors.[31] While a positive outlook would also lead to higher yields in the United States, it would also increase investors' risk appetite and simultaneously raise the expectation of positive spillover effects from the United States to the rest of the world. This would then result in rising gross inflows of funds to other countries as well. The positive information impulse thus leads to market reactions that are very similar to the effects of an increase in aggregate demand.

Monetary policy influences portfolio flows via two channels

An analysis by the Bundesbank on the functioning of these two channels shows that the

Impact of US monetary policy on international portfolio flows

International portfolio flows are influenced by different drivers, which the literature usually breaks down into international "push" factors and country-specific "pull" factors. One key structural driver is monetary policy in the United States, which ranks as a global determinant, or push factor, owing to the special role the United States plays in shaping financial conditions worldwide.

Empirical evidence indicates that a tightening of monetary policy in the United States leads to outflows of funds in the rest of the world, especially in emerging market economies.[1] This box takes a closer look at how exactly US monetary policy influences portfolio investment around the world, given that central banks influence capital markets not only by means of monetary policy measures themselves, but also via what are known as central bank information shocks. When central banks present their decisions and explain them in press releases or at press conferences, they also explicitly or implicitly share their own assessment of the economic outlook, which for investors might contain a new and surprising piece of information.

The effects of both these shocks – "pure policy" shocks and central bank information shocks – on portfolio flows can be estimated using proxy VAR models.[2] These models use instrument variables to identify the two shocks. Kerssenfischer (2019) shows how these instrument variables can be generated from high frequency data, using the scenario of a Eurosystem monetary policy shock. Applied to a monetary policy shock in the United States, the approach is based on changes in the two-year US government bond yield and percentage changes in the S&P 500 index within a relatively narrow window around announcements by the Federal Open Market Committee (FOMC). For the purposes of this analysis, the window is the day of the announcement: closing prices on the day of the announcement are compared with closing prices on the day before the announcement.[3] Thus, the investigation is based on the assumption that movements in equity prices and bond yields on the day of the FOMC announcement are driven primarily by the announcement itself. A (pure) policy shock can be expected to send equity prices and bond yields in different directions: taken in isolation, a contractionary monetary policy shock is likely to push up interest rates and dampen economic activity, probably causing bond yields to rise and equity prices to fall. A central bank information shock, by contrast, generally moves both variables in the same direction. Hence, a positive information shock – that is, an unexpectedly upbeat outlook for investors – can be expected not only to lead to rising interest rate expectations and bond yields, as with a pure policy shock, but also to have a positive effect on equity prices at the same time.

2 See also Deutsche Bundesbank (2020b).
3 Kerssenfischer (2019) uses a window of just a few minutes around announcements. This approach tends to improve the identification of shocks because it also means the effect can be disentangled from information that becomes known on the same day as the monetary policy decisions but at different times. However, this makes it more difficult for researchers without access to such data to replicate the results. Comparisons between shocks from high frequency data and daily data have shown that, in the present case, daily data provide tools that are good enough to clearly identify the shocks.

* Impulse response functions of fund flows following various monetary policy shocks. Shocks are normalised such that they increase the yield on US government bonds with a two-year residual maturity by 25 basis points. Fund flows are shown as the monthly change relative to total net assets at the start of the respective period. The respective percentage point change relates to this ratio.

Deutsche Bundesbank

Proxy VAR models are estimated using monthly data for the period from August 2005 to December 2021. These models are fed with variables that capture key elements of the US capital market: the S&P 500 composite index, the US dollar's nominal effective exchange rate (NEER), the VIX volatility index and the yields of US government bonds with a residual maturity of two years. In addition, a variable is added to each model to represent fund flows of investment funds investing in a given region and asset class.[4] Fund flow data are sourced from EPFR Global and serve as a proxy for balance of payments statistics on inter-

national portfolio investment, which are available at only a relatively low frequency in many countries.[5] The models are estimated using Bayesian methods.

The estimation results produced by the VAR models are presented in the form of im-

---

[4] The regions analysed here are advanced economies and emerging market economies. Economies are categorised according to their EPFR Global classification. The asset classes analysed here are equity funds and bond funds.

[5] EPFR data and balance of payments statistics are not exactly the same in conceptual terms. One reason for discrepancies between the data is that the EPFR data also capture transactions by residents, which are omitted from the balance of payments statistics.

pulse response functions of the fund flows in each case. The shocks are scaled such that the median of the posterior distribution of two-year yields increases by 25 basis points. This way, the effects of a contractionary monetary policy shock can be compared with those of a positive central bank information shock. Fund flow responses are summarised in the chart on p. 48, which shows the respective estimated changes in fund flows compared with total net assets at the start of the period in percentage points.[6]

The monetary policy shock triggers immediate and significant declines in the fund flows into bond funds investing in advanced economies (1.1 percentage points; median) and emerging market economies (3.6 percentage points). Hence, the effects in emerging market economies are significantly stronger.[7] The picture is mixed for equity funds, however, for two reasons. First, the evidence of a decline in fund flows into advanced economies is not significant. Second, the results indicate a significant increase in fund flows into emerging market economies. One possible reason for this observation could be reallocations into funds with higher risk premia in emerging market economies.

A much more uniform picture is presented by the estimation results for fund flows following a positive central bank information shock. A positive shock of this kind causes fund flows to increase significantly, irrespective of region (advanced economies versus emerging market economies) and asset class (equities versus bonds). Here again, fund flows into bond funds investing in emerging market economies show a much stronger response than those focused on advanced economies: the information shock causes fund flows into emerging market economies to increase by 3.4 per-

centage points, while those into advanced economies rise by 1.1 percentage points. As regards equity funds, the responses are significantly smaller and smoother, with fund flows into advanced and emerging market economies increasing by 0.3 and 0.4 percentage point, respectively.

The results show the importance of specifying a monetary policy shock as precisely as possible, because a pure policy shock can affect capital flows differently than a central bank information shock, even though both shocks induce an interest rate rise in the specification shown. If, for example, the role of monetary policy were identified only via an exogenous rise in interest rates, the estimation results could be distorted and result in incorrect economic policy conclusions being drawn.

6 Total net assets at the start of a period will not necessarily match those at the end of the previous one because new funds may have been added to the sample.
7 See, inter alia, Kalemli-Özcan (2019) and Koepke (2018).

Bundesbank study: US monetary policy influences portfolio flows via monetary policy impulses and information impulses

effects, approximated by flows to investment funds, can vary considerably (see the box on p. 47).[32] The impulses in the study lead to an assumed increase in interest rates of 25 basis points in each case. However, a contractionary monetary policy impulse causes investors to reduce their investments in bond funds, while a positive information impulse leads to increased inflows of funds. It makes no difference here whether the funds invest in advanced or emerging market economies.

Impact greater in emerging market economies than in advanced economies

In emerging market economies, the effects are much greater still:[33] a pure monetary policy impulse in the United States leads to a simultaneous decline in flows to bond funds in emerging market economies, equivalent to 3.6% of holdings. In advanced economies, this decrease amounts to 1.1% of holdings. New information results in a similar pattern among these two groups of economies, albeit with an inverted sign. In this case, flows to bond funds in emerging market economies increase by around 3.4% and in advanced economies by 1.1% of their holdings. As a result, this means that models that do not distinguish between the two channels only partially capture the impact of monetary policy on cross-border purchases of debt securities, or even provide a distorted picture.

Mixed findings for equity funds

With regard to equity funds, the results are less consistent. While new, positively received information does lead to an increase in fund flows in both groups of economies, monetary policy impulses trigger a decline in fund flows only in advanced economies. In emerging market economies, fund flows are seen to increase, which may be attributable to shifts toward funds with higher risk premia in emerging market economies.

Time variation in the importance of drivers of international portfolio flows

In the above considerations, it was implicitly assumed that the importance of the various drivers of portfolio flows remained constant over time, and any variation in their specific influence over time was not taken into consideration. However, this assumption may be too restrictive, for example due to information asymmetries, heterogeneity amongst investors, budget constraints, and reappraisals of risks. Moreover, in the case of individual variables, certain thresholds also play an important role.[34]

Various causes of time variation in the importance of drivers of portfolio flows

Information asymmetries: If the supply and demand sides possess different information about the intrinsic value of a security, it is not possible for the market to clear completely. The drivers of portfolio flows would shift depending on whether there is excess supply or demand.[35]

Information asymmetries

Heterogeneous investors: Domestic and foreign investors may have different investment motives. A change in the importance of individual drivers may therefore reflect the activity of different groups of investors.[36]

Heterogeneous investors

Budget constraints: Investors are, to some extent, tied to the specific risk profiles of managed portfolios. If the relevant specifications are violated, for example, due to financial market stress, this can lead to assets being sold off in the financial markets, which in turn can trigger further selling. As a result, the importance of risk measures may grow over time.[37]

Budget constraints

Reappraisal of risks: Investors and economists learn from economic changes. For example,

Variation in the importance of push and pull factors for portfolio flows over time

The extent to which portfolio flows are influenced by international (push) and country-specific (pull) factors has already been subject to both comprehensive and controversial discussion in the economic literature. A discussion paper recently published by the Bundesbank investigates the question of how the importance of these factors changes over time.[1] To this end, a Bayesian dynamic factor model with time-varying coefficients and time-varying stochastic volatility is estimated.[2] This model can be used to explain not only when certain factors were important for individual countries in the past, but also which factors are important at present. The approach is based on the idea that capital flows to individual countries can be broken down into a common component and a country-specific component. In this context, the model accounts for the fact that the weights of these components can shift over time. The common component is interpreted as a push factor and the country-specific component is interpreted as a pull factor.

For the analysis, portfolio flows are approximated using flows to investment funds, as these data are available earlier and at a higher frequency than balance of payments data. Monthly data on 26 emerging market economies and 21 advanced economies from EPFR Global are used for this purpose.[3] The observation period extends from August 2005 to September 2020. The investigation distinguishes between capital flows to advanced economies and those to emerging market economies. In addition, the data allow a distinction to be made between equity funds and bond funds. This results in four different variations, for each of which a factor model is estimated.

The objective of the factor model is to break down each individual time series under observation $(y_{i,t})$ into a common component, a

factor (f_t), and a country-specific component, residual $(\epsilon_{i,t})$:

$$y_{i,t} = a_i + b_{i,t}f_t + \epsilon_{i,t}.$$

The indices i and t represent the country and period under observation, respectively. The constant (a_i) refers to the specific country in question and is not time-dependent. By contrast, the factor can have a different impact on the respective fund flows for each country and at each point in time. The sensitivity of the fund flows to the factor is determined by the time-varying parameter $b_{i,t}$, which is assumed to follow a random walk:

$$b_{i,t} = b_{i,t-1} + \sigma_{\eta i}\eta_{i,t}.$$

The intensity of the time variation is defined by the term $\sigma_{\eta i}\eta_{i,t}$, where $\sigma_{\eta i}$ describes the variance and $\eta_{i,t} \sim N(0,1)$ is true.

Both the factor and the country-specific component follow autoregressive processes of order $p = 2$ and $q = 3$:[4]

$$f_t = \phi_{0,1}f_{t-1} + \ldots + \phi_{0,q}f_{t-q} + e^{h_{0,t}}u_{0,t}$$
$$\epsilon_{i,t} = \phi_{i,1}\epsilon_{i,t-1} + \ldots + \phi_{i,p}\epsilon_{i,t-p} + \sigma_i e^{h_{i,t}}u_{i,t}.$$

Here, $u_{0,t}$ and $u_{i,t}$ are the respective error terms. The autoregressive dynamics of the factor and the country-specific components are described using the parameters ϕ. In addition, the model also accounts for vari-

---

2 See Del Negro and Otrok (2008).
3 These fund data differ from balance of payments data in that they cover only a subset of the total portfolio flows and, at the same time, depict the total flows to funds that invest in a given country. This means that they also cover funds invested by residents.
4 The number of time lags corresponds to the specification in Del Negro and Otrok (2008). The lags account for the assumption that both the common and country-specific components represent macroeconomic variables as drivers of portfolio flows.

Deutsche Bundesbank

ation in the volatility $(h_{i,t})$ of the components over time, which follows a random walk:

$$h_{i,t} = h_{i,t-1} + \sigma_{\zeta i}\zeta_{i,t},$$

where $\sigma_{\zeta i}$ describes the variance and $\zeta_{i,t}$ $\sim N(0,1)$ is true.

The estimated factors (f_t) in the four models are shown in the adjacent chart. Both the global financial crisis in 2008 and the financial market turmoil at the start of the COVID-19 pandemic in March 2020 are captured by all of the models in the common push factors. This suggests that the model correctly recognises global events and allocates them to the appropriate factor.

However, the key question of this analysis is: "To what extent does each factor influence the flow of funds to each country?". In order to answer this question, the variance in fund flows is broken down into the contributions of each factor. The table on p. 52 shows the relative contribution of each factor to the variance in flows to equity and bond funds in selected countries. In this case, this approach reveals a high degree of heterogeneity with regard to the relative importance of factors within different regions and asset classes. The table shows the shares of the variance in each fund flow that can be explained by push and pull factors at various points in time for selected countries. For example, the relative importance of push factors for portfolio flows to advanced economies has increased over time – this holds especially true for EU Member States. With regard to portfolio flows in emerging market economies, the results vary significantly by region (advanced versus emerging market economies) and asset class (equities versus bonds).

One advantage of this approach is that it is agnostic when determining the international and country-specific drivers. Commonalities are interpreted as push factors, whilst all other aspects are considered to be

Estimated factors for flows to investment funds*

Deutsche Bundesbank

pull factors. This means that the factors are calculated in a purely statistical manner, which implicitly also takes account of variables that are unknown in the literature. For this reason, the results may differ from studies that focus on the importance of individual drivers.[5]

The model class presented here provides deep insight into the portfolio flows under observation not only with regard to their cross-section, but also into how they change over time. However, this comprehensive picture comes at a cost. Due to the considerable number of different parameters, the estimates are subject to a comparatively high level of uncertainty. This should be taken into consideration when interpreting the results.

---

5 See, inter alia, Fratzscher (2012) and Lo Duca (2012).

the global financial crisis also led to changes in modelling. Since the crisis, much more attention has been given to the real estate markets and the banking sector than had been before.

Thresholds

Thresholds: Certain variables may gain or lose importance for international capital flows if they exceed or fall short of specific thresholds. For example, foreign currency reserves contribute to the external stability of an economy, but, if holdings exceed a certain threshold, they may become less relevant as a variable for investors.

Estimating time variation is computationally intensive

It should therefore come as no surprise to find empirical evidence of shifts in the importance of drivers of portfolio flows. Nevertheless, the estimation methods for such matters are much more complex and have only recently gained in popularity.

Empirical studies sometimes resort to a temporal separation of samples

Before time variation was explicitly mapped in models, studies simply looked at individual time periods separately. For example, Fratzscher (2012) found that portfolio flows were heavily influenced by international drivers such as the TED spread at the time of the global financial crisis, while individual country-specific drivers gained in importance later on. In addition, the study also points to differences in the importance of drivers amongst individual countries. The fact that countries react to individual drivers to differing degrees can, for example, be attributed to the quality of institutions, country-specific risk, or macroeconomic fundamentals.

Major change in the importance of drivers following global financial crisis

Lo Duca (2012) published one of the first studies on portfolio flows to explicitly model time variation and found evidence of a change in the importance of individual drivers. In this context, the study established connections between flows and specific variables including confidence, credit risk in the interbank market, and regional developments in emerging market economies. The results of the study point to significant changes in the importance of individual drivers. Prior to the global financial crisis,

the regional macroeconomic environment played an important role in portfolio equity flows to emerging market economies. However, following the collapse of the US investment bank Lehman Brothers in 2008, there was a significant withdrawal of equity portfolio investment from these countries. According to Lo Duca's model, a loss of confidence among market participants set in at this time, leading to a change in the importance of individual drivers of portfolio flows.

A study recently published by the Bundesbank analyses the relative importance of push and pull factors for portfolio flows.[38] The study does not examine individual drivers, however, but instead statistically determines pull factors and push factors from the flows and views each set of factors collectively (see the box on p. 51). This approach is agnostic as far as the specific factors are concerned. The advantage of this is that no material determinants are overlooked. The results suggest that time variation is of particular significance, with a high degree of heterogeneity in the importance of the factors within different regions (advanced economies versus emerging market economies) and asset classes (equities versus bonds). For example, the importance of push factors for portfolio flows in many advanced economies has increased significantly over time – especially in EU Member States. By contrast, with respect to flows into emerging market economies, the picture is very heterogeneous.

Increased significance of push factors as a whole for EU Member States

▌ Conclusion

Portfolio flows are a key factor in the external interconnectedness of economies as well as in their economic development. This is because they contribute, amongst other things, to an efficient allocation of capital, enable investors to diversify their risk, and allow risk to be shared in the event of unforeseen events. However, notwithstanding the positive aspects,

---

38 See Bettendorf and Karadimitropoulou (2022).

close interconnectedness can also lead to external dependencies and help economic crises to spread more quickly. From an economic policy perspective, a sound understanding of the main drivers of capital flows is therefore essential.

Which variables have the greatest impact on portfolio flows depends on a number of criteria. The level of development (advanced economies versus emerging market economies) and the asset class (equities versus bonds) play key roles here. At the superordinate level, the respective drivers can be divided into global factors (push factors) and country-specific factors (pull factors). However, individual drivers affect portfolio flows both from a global economic perspective and from a country-specific perspective. In addition to other factors, such as economic developments, monetary policy also plays an important role, as it has a significant impact on the international interest rate environment and the risk assessment in the financial markets.

The results presented here suggest that the US Federal Reserve, in particular, has a significant impact on international portfolio flows (measured in terms of fund flows) through both pure monetary policy impulses as well as information impulses. A tightening of monetary policy that leads to an increase in the interest rate level in the United States can therefore influence investors' investment behaviour in different ways. While the monetary policy impulse, and the more challenging financing conditions for enterprises associated with this impulse, mean that there will tend to be a decline in flows to bond funds, the information impulse acts in the opposite direction. This is because the interest rate hike can be interpreted as a signal from the central bank that it expects an economic upturn. The impact of both impulses is stronger in emerging market economies than in advanced economies. For equity funds, the results are inconsistent.

Moreover, the importance of push and pull factors appears to be subject to significant time variation. For example, estimation results indicate a high degree of heterogeneity with regard to the importance of factors in different regions (advanced versus emerging market economies) and asset classes (equities versus bonds). The importance of push factors for portfolio flows in many advanced economies has increased over time – especially in EU Member States. With respect to portfolio flows to emerging market economies, the results are highly heterogeneous between individual countries. This is in line with the academic literature, which indicates that investors are increasingly differentiating between individual emerging market economies.

Cross-border interoperability of central bank digital currency

The digitalisation of the economy, flourishing online commerce, global supply chains and migration are making cross-border payments more and more important. Compared with domestic transactions, payments across the borders of currency areas are more expensive, slower, less widely accessible and less transparent. This is particularly true of payments by individuals and enterprises. Central bank digital currency (CBDC) could help to overcome these obstacles.

As CBDC would inevitably necessitate the development of new infrastructures, it could act as a catalyst for enhancements in the cross-border payments space. Examples of such improvements would be the use of common message standards along the entire payment chain and faster settlement due to shorter process chains made up of fewer participants. Likewise, CBDC could present an opportunity to integrate currency exchange functionality into payment settlement. CBDC for financial institutions (wholesale CBDC) could also improve liquidity management in cross-border payments. In addition, programmable interfaces could help to link CBDC systems with one another or with other financial market infrastructures.

A multilateral approach is most likely to enable CBDC to help reduce the frictions currently hampering cross-border payments. This would involve central banks providing CBDC for use in their own currency area, but facilitating cross-border payments through interoperability of their own CBDC infrastructure with other payment systems. Such an approach would avert the macroeconomic risks associated with a unilateral approach whereby, outside of its domestic market, a currency area's CBDC would be held and used as a foreign currency. Depending on the extent of cooperation, a multilateral approach in the form of compatible systems, interlinked systems or a common platform could open up varying degrees of potential for faster, cheaper and more transparent payment settlement.

A higher degree of interoperability requires close cooperation between the central banks involved. Differences in legislation and national standards for data handling or cyber security provisions can hinder efforts towards greater interoperability. Differing national interests, fears over losing autonomy and control, and a lack of confidence in joint governance structures may also pose barriers to increased international cooperation.

The G20 countries have set 2027 as their target date for improving cross-border payments. As things currently stand, CBDC is unlikely to be able to make a meaningful contribution in the near future. In the medium term, however, the development of CBDC will provide a favourable foundation for establishing interoperability between payment systems through stronger cooperation among central banks; this offers prospects for mitigating the effects of the global retreat of correspondent banks. For that to come to fruition, central banks' work to develop CBDCs needs to be geared towards international usage and common standards from the outset.

Introduction

The importance of cross-border payments is growing, …

A combination of factors has driven a dynamic evolution in international payments over recent years.[1] Irrespective of the current disruptions, global supply chains have led to a growing number of payments between firms in different countries. Increasing migration generally leads to a growing number of credit transfers being made by migrants to family members in their home countries (referred to as remittances) that constitute a significant inflow of funds for numerous countries relative to gross domestic product (GDP). New modes of working, increasing international tourism and the rise in international trade fuelled, in part, by e-commerce are making cross-border retail payments more and more important.[2] However, when it comes to settlement, which is predominantly conducted via correspondent banks and money transfer services (such as Western Union, MoneyGram and the like), there is significant room for improvement.[3] With this in

mind, talk has now also turned to whether and how CBDC might contribute to efficiency gains.

For some years now, cross-border payments have additionally been suffering from the complete or partial retreat of financial institutions from correspondent banking activities in an effort to de-risk. Business relationships have been terminated, with the mounting costs of regulatory compliance being one of the motivating factors. The number of such links has fallen by almost one-fifth since 2011 and has made for significantly weaker competition. Particularly hard hit by the decline in correspondent banking relationships have been the regions of Africa, Latin America and Oceania, where some countries are heavily dependent on incoming remittances.[4]

… whilst, at the same time, banks are retreating from this business

Diminishing competitive intensity could ultimately lead to higher prices. There is also the risk that payment channels between certain countries will end up shut down altogether, leaving some regions entirely cut off from global payments. Last but not least, the dwindling of correspondent banking relationships could fuel recourse to payment channels that are less closely regulated and monitored (e.g. cash transfers or crypto-tokens).

Frictions in cross-border payments and objectives for reducing them

Settlement of domestic payments has improved significantly in many countries in recent years; by contrast, cross-border payments are generally more expensive, slower, less transparent and are often only accessible to a smaller set of users than domestic payments. Having said that, this does not hold true for payments within the euro area, where – facilitated by a single currency – substantial investment has

gone into integrating national payment systems and creating a single European market for payments.

A number of frictions are causing these inefficiencies

As part of its work to enhance cross-border payments, the Financial Stability Board (FSB)[5] has pinpointed areas of friction that play a major role in the existing inefficiencies, which include high costs, low speed, limited access and limited transparency.[6]

– Fragmented and incomplete data: the use of fragmented data formats for the transmission of payment data means that important information – such as the know your customer (KYC) data essential for verification of the payer or recipient – sometimes does not get transmitted or is only communicated in truncated form. This makes automating payment processing more difficult and pushes up the cost of the transaction if the payment requires some manual processing.

– Complex compliance checks: different legal frameworks for the prevention of money laundering and terrorist financing lead to additional costs for the participants in the payment chain, and these are passed on to the end users.

– High liquidity costs: the complexity of the correspondent banking relationships between the institutions involved means the need for liquidity in various currencies is high; this entails commensurate costs.

– Frictions at settlement level: legacy technology, limited opening hours and long trans-

5 The FSB is an international body tasked with identifying any vulnerabilities in the international financial system and proposing and monitoring implementation of any action needed to address them. Its members include the central banks, supervisory authorities and finance ministries of the G20 countries as well as Hong Kong, the Netherlands, Spain, Singapore and Switzerland.
6 See Financial Stability Board (2021b). See also McKinsey and SWIFT (2018) for a look at the types and amounts of the various costs involved in cross-border payments.

G20 countries' targets for enhancing cross-border payments

Challenges	Payments segment		
	Payments between financial institutions (wholesale payments)	Payments between individuals and businesses (retail payments)	Remittances
Cost	No target set.	By the end of 2027, global average costs to be limited to 1% of payment amount. Costs no higher than 3% in any corridor.	By 2030, global average cost for a transfer of US$200 to be no higher than 3%. Costs no higher than 5% in any corridor.
Speed	By the end of 2027, 75% of cross-border payments to be settled within one hour, with the remaining 25% settled within one day.		
Access	By the end of 2027, all financial institutions to have at least one option (several, if possible) for engaging in cross-border payments.	By the end of 2027, all end-users to have at least one option for engaging in cross-border payments.	By the end of 2027, more than 90% of people (including those without a bank account) to be able to use electronic payment services for remittances.
Transparency	By 2027, all payment service providers to supply both the payer and the payee with a minimum standard of information regarding cross-border payments: (i) transaction costs (all costs along the payment chain, exchange rates and currency conversion fees); (ii) the expected time to deliver the funds; (iii) tracking of payment status; and (iv) terms of service.

Deutsche Bundesbank

action chains increase processing time and costs and make international payments less transparent.

Ultimately, these frictions also contribute to high barriers to market entry, resulting in the lack of competition in the cross-border payments space that we have already mentioned.

G20 have formulated targets to be achieved by 2027

In 2020, the G20 countries devised a roadmap with a view to addressing and eliminating the frictions described above. It consists of 19 building blocks that fall into a total of five focus areas. These include global harmonisation of regulatory frameworks, improvements to data quality, the expansion of existing payment infrastructures and the development of new infrastructures, as well as the definition of a common vision for enhanced cross-border payments.

As part of this common vision, concrete objectives for the various segments of cross-border

payments have already been set, with the target of achieving them by 2027 (see the overview above). They address payments between financial institutions as well as retail payments, plus remittances, which are usually listed separately.

The goal is for payments by individuals and businesses to not cost any more than 1% of the transaction value and for the cost of remittances not to exceed 3% of the amount being transferred. Furthermore, 75% of all payments should be available to the payee within one hour. In addition, certain information is to be made transparent to payers and payees, such as the total cost of the transaction and the time it will take to settle.[7] Alongside the efforts of central banks and legislators, private sector initiatives can also help to achieve the objectives set by the G20 countries.[8]

7 See Financial Stability Board (2021).
8 For example, initiatives such as SWIFT gpi and SWIFT Go are intended to make for speedier and more transparent international payments.

Central bank digital currency – a new start?

CBDC is being explored throughout the world

The crux of the structural problem with international payments lies in the fact that such payments have to pass through several domestic payment systems with different designs (normally, the country where the payer is sending the funds from and the country of the payee). On top of this, a bridge (e.g. in the form of correspondent banking) is usually necessary as well to provide the technical connection between both systems and, where necessary, perform any currency exchange. Against this backdrop, investigations are currently under way looking at whether and how CBDC will open up options for creating new structures and thus the possibility of placing cross-border payments on a common footing.

Discussions around CBDC have gained noticeable momentum in the last few years. A survey conducted by the Bank for International Settlements (BIS) found that around 90% of the respondent central banks are exploring CBDC. One-third are at the pilot phase or already in development.[9] Work is going into both wholesale CBDC[10] and retail CBDC.[11] Initiatives are being motivated by different drivers in individual cases, with financial inclusion, monetary sovereignty and increased efficiency of domestic payments among the reasons cited. However, the desire for more efficient cross-border payment transactions is also playing into the central banks' efforts.

The Eurosystem is currently investigating the feasibility and possible design of a digital euro in the form of a retail CBDC. The ongoing investigation phase is set to run until October 2023 and reach a conclusion as to whether a digital euro should actually be developed and issued.[12]

Cross-border payments play a role in deliberations about CBDC

CBDC will not just be a means of payment; it will also require an infrastructure enabling issuance and circulation. For CBDC to be used in cross-border transactions, establishing interoperability between individual CBDC infrastructures is a must – in other words, they need to be able to work together as seamlessly as possible. Pilot phase CBDC projects being pioneered by central banks are concentrating on wholesale CBDC, with a focus on international payments in the interbank market (e.g. the Dunbar and mBridge projects described below). There are also initiatives in the private sector that are looking to create infrastructures for the cross-border use of wholesale CBDC (J. P. Morgan Onyx,[13] for instance).

Yet enhancing the cross-border payments landscape is also an important motivator behind retail CBDC projects, especially for emerging market and developing economies.[14]

However, the majority of retail CBDC projects are currently geared more towards domestic payments, as the development of CBDC, even in the domestic context, raises numerous issues of a conceptual, technical and legal nature. Moreover, the timeframes that most of the projects are working with are unlikely to be compatible with the deadline set in the G20 roadmap. Nevertheless, it is still imperative that cross-border payments be included from the outset in the thinking going into designing CBDC. The new CBDC systems will only be able to aid in enhancing cross-border payments in future if they are interoperable. As well as generating stiffer competition by offering an additional settlement channel, CBDC and its unique technical design could enable efficiency gains

Interoperability beyond the G20 roadmap is important

---

9 See Kosse and Mattei (2022).
10 In this context, wholesale CBDC describes a CBDC which is primarily designed for use in payments between credit institutions/financial market infrastructures.
11 Retail CBDC describes a CBDC which is designed to be used for payments by non-banks (e.g. the public, enterprises, public authorities).
12 The European Central Bank (ECB) is part of a consortium of eight central banks looking into the basic design of CBDC. Cross-border payments are one of the aspects feeding into their considerations. See Bank for International Settlements (2020).
13 J. P. Morgan Onyx is a blockchain platform for exchanging payments, digital assets and payment information.
14 See Kosse and Mattei (2022).

that are difficult – if not impossible – to attain using traditional instruments.

Ways in which central bank digital currency could mitigate frictions

Development of new structures can enable CBDC to act as a catalyst for smoothing frictions

Some of these efficiency gains can be achieved through the "accelerant" effect of new systems, as they promote a reinvention of the system landscape with the cross-border dimension in mind.[15] The scope for improving existing systems could be limited if expanding their functionality takes them to the bounds of what is technically feasible or if the costs of adapting them are higher than those of developing a new system. Meanwhile, the development of new payment settlement infrastructures can present a host of advantages that, over the medium term, outweigh the short-term investment costs. In many countries, CBDC systems are being developed precisely with the aim of increasing financial inclusion. This opens up the possibility of simultaneously expanding access to cross-border payments as well. Depending on how a given CBDC is designed, payment service providers that have so far been dependent on the services of banks could take on a greater role in the settlement infrastructure. Banks, too, could provide new services. For those banks that engage in international correspondent banking, the incentive to improve or participate in new systems would depend on how potential new income might measure up against the potential loss of previous business. Overall, competition at the customer interface could intensify and more innovative services could be offered.

New data standards and real-time settlement can increase efficiency

Newly developed systems can ensure efficient and transparent data processing through, for example, the application of uniform messaging standards.[16] This could cut down the need for (costly and time-consuming) manual intervention at the individual stages of the payment chain. In addition, transactions could be settled directly and in real time.[17] This would mean that payers and payees, in cross-border payments especially, could receive confirmation of successful settlement in a matter of seconds, which would minimise costs associated with risk monitoring and hedging. That would directly address two key challenges – a want of transparency and the high costs – where cross-border usability is concerned.

Integration of currency exchange functionality could generate significant efficiency gains

However, this would require currency exchange functions to be built into CBDC systems from the outset. This could be done, for example, via selected third parties or a market mechanism that is also incorporated into transaction settlement in real time.[18] Currency exchange in real time, enabled by the use of a wholesale CBDC, would – for example – serve to mitigate the issue of liquidity management in cross-border payments. In this way, wholesale CBDC could also support alternative private sector solutions for improving cross-border payments.

New systems for CBDC may encourage harmonisation of technical and legal standards

At the same time, new CBDC systems could encourage a harmonisation of legal frameworks or settlement standards. Besides the shared messaging standards[19] already mentioned, that might include, for example, more homogenised conditions for access to payment systems, harmonised rules for establishing settlement finality and extended operating hours for payment systems. CBDC could also prove to be a catalyst for digitalisation initiatives in the payments sphere.[20] In the European Union, for instance, CBDC forms part of the general digitalisation strategy, which also includes the interoperability of digital identities. In ths context, Member States have been called upon to cre-

---

15 See Bank for International Settlements (2021a).
16 For example, ISO 20022, which establishes a uniform standard for payment messages.
17 In correspondent banking particularly, the large number of parties involved in settlement mean that transactions can sometimes be hard to track. It is not possible for the payer and payee to check the whereabouts of a payment at all given moments. SWIFT has just recently successfully introduced the SWIFT gpi initiative, providing better tracking of transactions in the SWIFT network.
18 See European Central Bank (2021).
19 For example, ISO 20022 (https://www.swift.com/standards/iso-20022).
20 See Bank for International Settlements (2022b).

ate a toolbox for the provision of digital identity wallets, which could also be used for payments and the digital euro.[21]

Open interfaces could lend a significant boost to interoperability with other systems

The implementation of open interfaces would offer further advantages. From a technical perspective, this could be done using, say, application programming interfaces (APIs)[22] or trigger solutions,[23] enabling, for example, payment-versus-payment settlement in different currencies. Payment-versus-payment settlement in international transactions minimises settlement risk for buyers and sellers, since the funds denominated in different currencies change hands simultaneously.[24] With the help of such setups, CBDC systems could be made interoperable without a huge amount of effort, or could simplify international capital flows by means of linkages to securities settlement systems, for example. Open interfaces would also allow new CBDC systems in one country to be linked to traditional payment systems in another country. This could enable differences between countries and regions in terms of their development paths and the solutions that they are pursuing to be accommodated.

International central bank digital currency: multilateral cooperation instead of unilateral issuance

International CBDC: unilateral approach or multilateral cooperation

Many of the outlined opportunities of using CBDC to mitigate current frictions in cross-border payments assume a certain degree of international cooperation among central banks. A multilateral[25] approach of this nature could, in particular, see participating central banks issuing local-currency CBDC to be primarily held by residents of their currency area.[26] Cross-border payments would be made possible through the above-mentioned interoperability with other CBDC systems. By contrast, it would be possible to follow a fundamentally different approach, whereby central banks issue CBDC unilaterally and design it in such a way that it

can be held across borders and be used internationally.

Under a unilateral approach, cross-border payments would therefore be made within a single, closed payment system in a single, digital currency. There would be no need for interoperability with other CBDC systems in order to transfer money across national borders and no need for a currency exchange mechanism within the system. In practice, however, an option for converting foreign-currency CBDC into the respective national currency following a cross-border transaction would be required. Foreign payment service providers, for example, would also have to maintain foreign-currency accounts. This could result in additional costs for the end user, especially in situations where the foreign-currency CBDC could not be used to pay for goods and services abroad. A unilateral approach would therefore not be able to do away with a link to foreign payment systems entirely either; rather, such a link would be placed in the hands of private agents.[27]

Unilateral approach: no need for interoperability between CBDC payment systems, …

In addition, from an economic perspective, a number of risks place a question mark over the usefulness of a unilateral approach. At first glance, these primarily concern those countries in which CBDC would be used as a foreign currency but, on closer inspection, also the currency area issuing the CBDC.

… but associated with a number of economic risks

If foreign-currency CBDC were to be used as a means of payment, for example a digital US

---

21 See European Commission: European digital identity (https://ec.europa.eu/info/strategy/priorities-2019-2024/europe-fit-digital-age/european-digital-identity_en).
22 APIs are programming interfaces that allow regulated access to the systems of the respective parties. In Europe, these are regulated, inter alia, by the Payment Services Directive (PSD 2).
23 See Deutsche Bundesbank (2021a).
24 See Deutsche Bundesbank (2021b).
25 This approach includes a conceivable bilateral solution.
26 It may also make sense to make domestic CBDC available to non-residents spending time in the country (e.g. tourists).
27 Major card companies and IT service providers have already launched initial projects heading in this direction.

dollar in the euro area, the domestic economy would be more affected by foreign economic developments. Model-based analyses, for instance, demonstrate that spillovers of economic shocks to the domestic economy are amplified in such cases. Domestic monetary policy would then have to respond to external developments to an increasing degree in order to stabilise economic and price developments at home.[28] At the same time, the scope for conducting effective monetary policy could be narrowed. To the extent that usage of CBDC as a means of payment also leads to the foreign currency being increasingly used as a unit of account at home, domestic monetary policy would lose force: if prices and wages are increasingly expressed in foreign currency, it will become more and more difficult for the central bank to use monetary policy measures to influence domestic prices and economic activity.[29] Not least for this reason, a central bank's unilateral effort to ensure that its own CBDC can be used internationally could be perceived abroad as undermining domestic monetary policy autonomy.

However, the expanded use of CBDC abroad would also have significant consequences for the central bank issuing the CBDC that can be used internationally. As CBDC is a liability of the issuing central bank, demand for CBDC from abroad would generally further extend its balance sheet. As a consequence, balance sheet risks would tend to increase. If the central bank were to issue CBDC against a foreign currency, for example, and build up foreign-currency holdings accordingly, its balance sheet would be more vulnerable to exchange rate fluctuations. In addition, such transactions would be the equivalent of foreign exchange market interventions at the expense of its own currency and, as such, subject to the commitments pledged by the G7 Finance Ministers and Central Bank Governors.[30] If, on the other hand, the central bank were to hold additional assets in its own currency, the value of its currency would tend to rise as a result of the additional demand from abroad. This, in turn,

could have negative consequences for the competitiveness of the domestic economy.[31,32]

If several central banks were to adopt a unilateral approach at the same time, this could ultimately also have a knock-on effect on their own ability to conduct monetary policy. If each country's CBDC is freely available abroad, foreign-currency means of payment would compete directly with domestic forms of money in all countries. Model-based analyses suggest that such currency competition could tend to lead to a convergence of interest rates

28 Ferrari Minesso et al. (2022) model the unilateral issuance of CBDC abroad, which can also be used for domestic payment purposes. As the foreign-currency CBDC increases the stock of foreign-currency assets held by domestic residents, any adjustment in response to exchange rate movements is stronger. This amplifies economic spillovers from the country issuing the CBDC and triggers a stronger domestic monetary policy response in the model.
29 Ikeda (2020) models such a "digital dollarisation" in which domestic prices and wages are denominated in foreign currency. Domestic monetary policy becomes less effective as digital dollarisation deepens, while the monetary policy of the foreign country that issues the digital currency used in the home country has a greater impact.
30 The communiqué from the G7 Finance Ministers' and Central Bank Governors' Meeting held in Bari, Italy, on 12 and 13 May 2017 states: "1. […] We reaffirm our existing G7 exchange rate commitments to market determined exchange rates and to consult closely in regard to actions in foreign exchange markets. We reaffirm that our fiscal and monetary policies have been and will remain oriented towards meeting our respective domestic objectives using domestic instruments and we will not target exchange rates for competitive purposes. We underscore the importance of all countries refraining from competitive devaluation […]". In the London communiqué of 5 June 2021, the G7 reaffirmed their adherence to these commitments.
31 Even in such a case, additional balance sheet risks may arise for central banks. This occurs when the stock of safe assets in its own currency is limited, necessitating the holding of increasingly risky securities.
32 If issuing CBDC were to lead to prices and wages being chiefly denominated in the domestic currency abroad, too, a currency appreciation would not have a significant impact on the domestic economy's competitiveness. This is because, for countries that predominantly use the same currency as a unit of account and as a means of payment, exchange rate fluctuations in another currency, which is hardly used for these purposes anymore, are generally less important.

between countries.[33] Instead of increasing their own international monetary and economic policy influence, such a system could actually narrow the scope for all participating central banks to conduct an independent monetary policy. The impossible trinity of international economic policy[34] could morph into a dilemma: although exchange rates could continue to fluctuate, were capital to move freely across borders, there would be less scope for independent monetary policy.

Restrictions could help to avoid risks, but they could run counter to the desired improvements

The above-mentioned risks associated with a unilateral approach could, in principle, be mitigated by designing the CBDC appropriately.[35] Indeed, debate in the euro area on potential caps for holding a possible digital euro (holding limits), for example, suggests that such restrictions may also be necessary in an international context. If, for example, the volume of domestic CBDC held abroad were to be strictly limited or if transactions were to be capped, the side effects would also be contained. Such restrictions, however, would run counter to the aim of using CBDC to address frictions in cross-border payments in the first place.

Multilateral cooperation approach preferred

For these reasons, instead of proceeding unilaterally, a multilateral approach could prove better suited to realising the potential of CBDC for cross-border payments. The participating central banks would then issue CBDC primarily in their own currency area,[36] but would make it interoperable across borders. Since large-scale holding or use of CBDC in foreign currency would not be envisaged, the macroeconomic risks of a unilateral approach would not arise.

These considerations apply to both retail CBDC and wholesale CBDC. For example, all current projects that use wholesale CBDC to simplify cross-border payments are characterised by strong multilateral approaches. These projects are also examining whether, for the purpose of simplifying payments, it would make sense to open up access to CBDC to foreign banks. If this were to happen, it would no longer be necessary to involve another bank in the recipient country. The experiments have generally shown that the issuing central bank would technically be able to obtain complete transparency about the CBDC held by foreign banks and implement various control and steering measures that enable a politically desired cap on wholesale CBDC circulating abroad. At present, however, in many countries access to central bank ac-

---

33 Benigno et al. (2022) model the impact of a global crypto-token that can be used internationally for payment purposes and thus competes with currencies issued by central banks. Because the token can be freely converted across national borders, changes in the value of the token in one of the countries have a direct impact on the exchange rate of the currencies to each other. Benigno et al. (2022) show that, while the currencies of the individual countries therefore do not compete directly, they may well do so indirectly. Under the model assumptions, this leads to a forced convergence of bond yields, i.e. the opportunity cost of holding money, between countries if the agents maintain equilibrium holdings of both the crypto-token and the respective local currency. In the model, this could only be avoided if central banks were to deviate from interest rate equality and lower their rates – which could lead them to the zero lower bound at which they would be unable to lower rates further. The outcome of this model can be applied to the context of international CBDC: if CBDC that can be used abroad were to compete directly with the respective domestic currency – not indirectly through a global crypto-token – interest rates would also tend to converge. The more similar the various forms of money in the model are, i.e. the more substitutable they are as means of payment from the user's perspective, the more this holds true.
34 In the economic literature of open economies, the impossible trinity describes the inability to simultaneously achieve the three potential objectives of free capital flows, fixed exchange rates and independent monetary policy.
35 In the model employed by Ferrari Minesso et al. (2022), described in footnote 28, for example, transaction restrictions for users of CBDC abroad mean that economic shocks from the country issuing the CBDC are transmitted less strongly across national borders.
36 Depending on the technical design, limiting the use of domestic CBDC to residents could be complex at an operational level, but so too would be implementing reliable identity and anti-money laundering controls for non-residents. If, for example, the CBDC is made available as a hardware token or in a purely decentralised network based on distributed ledger technology (DLT), it will be virtually impossible to restrict usage to a certain user group. By contrast, an account-based CBDC or a software token in a permissioned DLT network will enable usage to be restricted, for example, by refusing to open an account or set up a wallet as part of an identity check. Cross-border interoperability is likely to ensure that restricting usage to residents is not perceived as unduly restricting the free flow of capital. It will also be essential to ensure that the differing ways of treating various forms of central bank money do not give rise to a difference in value between cash and CBDC. The points outlined here also apply to the unilateral approach whereby, as mentioned above, at least a partial restriction of CBDC usage abroad would probably also be appropriate.

counts is restricted to domestic banks for risk, supervisory or monetary policy reasons.

Options for interoperable central bank digital currency

The concrete design of interoperability within the framework of a multilateral approach could take several forms.[37] The appropriate concepts can be roughly divided into three categories, although the distinction between them is not always clearly delineated:[38]

– compatible CBDC systems;
– interlinked CBDC systems;
– a single CBDC system.

Compatible systems

Compatible systems limit interoperability to compliance with common technical standards and harmonised legislation

The first option comprises CBDC systems that operate independently but are compatible. Interoperability is limited to compliance with common technical standards and, where necessary, harmonised legislation.[39] Common technical standards, such as those relating to message formats, cryptographic techniques and user interfaces, can reduce the operational burden on those involved.[40] Harmonised rules and standards simplify, for example, know your customer (KYC) and transaction monitoring processes. In principle, this applies both to CBDC and to private sector providers' means and methods of payment.

Despite these advantages, in practice there are major obstacles to overcome before systems are compatible, although these are probably smaller than those described below. This is because common standards can only be drawn up in joint coordination processes which, in turn, produce coordination costs. In addition, implementing common, uniform message standards can take years, as the example of ISO 20022 has shown. In 2004, the International Organization for Standardization (ISO) already published the 20022 standard for financial

messages with the aim of harmonising cross-border payments and improving communication between stakeholders. In 2025 – 21 years later – it is due to be used across the board as a universal standard, at least in large-value payment systems.[41] At the same time, work on the G20 roadmap mentioned at the beginning of this article is aiming to harmonise the application of ISO 20022. Simply having a common standard does not necessarily mean that it is interpreted in the same way globally.

Yet at the same time this option still requires recourse to correspondent banking or alternative mechanisms in order to transfer a payment from one system to another.

Interlinked systems

Systems can be linked using interfaces and common clearing mechanisms

The second option is to link various CBDC systems. This would enable a participant to make a payment from one CBDC system directly to a participant in another CBDC system without having to participate in the other CBDC system themselves. Such a set-up requires common technical interfaces and standards that enable information to be exchanged and thus payments to be made across different systems.

In addition, settlement could be simplified by using a central clearing agent to transfer payments to the other system or a common clearing mechanism. Such a clearing mechanism

37 Interoperability can and should, in principle, also be established with systems other than those for CBDC. However, this article focuses solely on cross-border cooperation between CBDC systems.
38 See Bank for International Settlements (2021a).
39 Central banks in six countries (Canada, Japan, Sweden, Switzerland, the United Kingdom and the United States), the ECB and the BIS have already begun to collaborate on fundamental questions regarding the design of CBDC; see BIS (2020). In future, initiatives such as these could form the basis of a cooperative approach or further-reaching joint activities.
40 In order to settle transactions, it may be necessary for at least one agent to participate in both systems as a liquidity provider.
41 As part of the TARGET2/T2S consolidation project, ISO 20022-compliant messages will be used across all TARGET services from November 2022 onwards.

Interoperability approaches for CBDC systems

Hybrid approaches

Compatible systems

System A
Separate rulebook and governance arrangements, participation criteria and infrastructure

Multitude of privately offered correspondence and clearing services | Formulation of joint standards

System B
Separate rulebook and governance arrangements, participation criteria and infrastructure

Interlinked systems

System A
Separate rulebook and governance arrangements, participation criteria and infrastructure

Interfaces and common mechanisms that build on these (contractually agreed)

System B
Separate rulebook and governance arrangements, participation criteria and infrastructure

Single system

Single system
Single rulebook and governance arrangements, single set of participation criteria and participants, single infrastructure and ledger

Degree of interoperability / efficiency benefits / challenges / operational risks

Deutsche Bundesbank

could, for example, be designed in such a way that payments are booked via settlement accounts with a central agent. It would, for instance, keep accounts in different currencies for the participating central banks.[42] The alternative would be a decentralised approach in which each participating central bank holds accounts with all the other central banks. When currencies need to be exchanged, the central banks could either do this themselves or with the help of private sector intermediaries. This means that, if necessary, the central bank from whose currency area a payment request in CBDC is made would exchange the corresponding amount on the foreign exchange market and ultimately have it credited to the central bank in whose currency area the payee is located. The amount would then be credited to their account in local-currency CBDC.

The introduction of common mechanisms, such as technical interfaces, faces hurdles similar to those to agreement on uniform stand-

ards in the first option. It should also be borne in mind that the direct technical linking of the systems would require a much higher degree of detail within the necessary agreements.

Interlinked systems are being tested, for example, as part of the "Jasper-Ubin"[43] and "Jura"[44] projects, which look at the cross-border use of wholesale CBDC. Both projects show how transactions on interface-linked DLT systems can be synchronised over time to reduce, for instance, the risks – and thus the costs – of cross-border transactions involving multiple currencies. The Jura project successfully tested the cross-border purchase of a DLT-

based security against wholesale CBDC in euro (delivery-versus-payment), followed by an exchange of the euro against wholesale CBDC in Swiss francs (payment-versus-payment). Technically, the security and the respective CBDC are issued on sub-systems, which in turn are linked via a common platform, with central banks retaining control over the issuance of their respective CBDC and the authorisation to participate in their sub-system.

Single system

Single CBDC systems in the form of multilateral platforms

The third option is based on the idea of a single CBDC system as a multilateral platform. As a general rule, it is not necessary to ensure compatibility or to link different CBDC systems. Instead, the concept provides for a single rulebook, a single technical system and a single set of participation criteria. Operators could be international institutions, a consortium of central banks, or a public-private partnership of central banks and the private sector. Given that the use of CBDC is to be seen as an integral component of this, platforms that are operated solely privately are unlikely to be an option.

Such a platform could have a single settlement currency or be capable of processing multiple currencies. If in the first case the single settlement currency were a national currency, such a system would have the properties of a unilateral approach. This system would thus also share the macroeconomic problems of unilateral approaches described above. If, on the other hand, a supranational settlement currency of its own were envisaged, fundamental questions would arise, such as what amount of such a currency would be issued and according to which rules. For these reasons, the current deliberations are focusing instead on multi-currency platforms. One advantage of using DLT could be that it would have a single technical platform with a single rulebook, yet still include decentralised elements, if necessary, and could provide some independent operational scope for the parties involved. Like in the Jura project, sub-networks could exist, but they would be more strongly integrated than systems linked via the common platform. Even in the case of multi-currency platforms, it would still be necessary to find a way for currency to be exchanged in cross-border transactions. One of several options is the automated market-maker using wholesale CBDC described in the box on p. 71.

Single systems are likely to offer their users greater operational functionality and efficiency than the options described above. Owing to the high degree of integration, a large number of the advantages of using CBDC in cross-border payments as described above could be achieved as no cross-system communication would be necessary for the individual transactions. At the same time, however, this increases the initial investment and the coordination costs between the parties involved in order to set up the system and to establish the requirements for common governance. The mBridge[45] and Dunbar[46] projects are practical examples of conceptual studies for single systems, i.e. multi-currency DLT platforms based on wholesale CBDC. The innovative settlement of cross-border and cross-currency transactions aims to reduce transaction costs, settlement times and operational complexity.

Hybrid systems

Forms combining different options could prevail

It is not always possible to distinguish clearly between the individual options, however. Hybrid approaches combining elements of the various options are therefore also conceivable in principle. For example, a single system could

46 The Dunbar project is operated by the BIS Innovation Hub Singapore Centre, the Reserve Bank of Australia, Bank Negara Malaysia, the Monetary Authority of Singapore and the South African Reserve Bank. See Bank for International Settlements (2022a).

Automated market-makers

Apart from involving central banks or private intermediaries, currencies could, in principle, also be exchanged via automated market-makers (AMMs) on a common system for central bank digital currency (CBDC) based on distributed ledger technology.[1] AMMs could be integrated into the software protocol of such a system and automatically process currency exchange.

This involves banks provisioning an omnibus account with liquidity in the form of CBDC, which, in turn, can be withdrawn by other participants in exchange for other CBDC. This would mean liquidity would be centrally available to all participants, which could lead to a particularly good liquidity allocation within the system, without participants being dependent on intermediaries.[2] AMMs are already used as part of decentralised trading platforms in the decentralised finance sector. Nevertheless, practical problems may arise. One key challenge is in designing an appropriate incentive system that encourages banks to provide liquidity. On the one hand, banks would receive "liquidity tokens" for the funds that they have contributed, via which, in turn, the fees accrued for trades are distributed – as compensation and an incentive to provide liquidity. On the other hand, liquidity providers also bear the risk of price changes when it comes to re-exchanging the liquidity tokens for the funds that they have contributed. This is because trading transactions add an asset (e.g. a currency) to the omnibus account, while the respective other asset is withdrawn from it at the same time. The transaction therefore shifts the volume ratio of the tokens in the omnibus account. On the basis of an algorithm, these changes lead to opposing price changes. The price of the added asset de-creases and the price of the withdrawn asset increases, whereby the user who carried out the exchange loses out (slippage loss). Prices therefore do not necessarily reflect supply and demand in the market, but rather encourage users to carry out opposing arbitrage transactions in order to restore the original volume ratio. The greater the shift an exchange transaction produces in the value ratio of a trading pair, the greater the slippage loss. It is therefore important that the omnibus account is sufficiently large, especially for less-traded currencies.[3] The incentive problem described above is one of the obstacles that would have to be removed before AMMs could potentially be used in a CBDC system.

2 See Bank for International Settlements (2022a).
3 See Deutsche Bundesbank (2021b).

be used within a region, which, in turn, is linked bilaterally to CBDC infrastructures in other countries. In practice, such hybrid systems could play a greater role in the future, especially because diverging national interests may make global agreement on a single approach appear unrealistic and possibly not even be desirable. It is more likely that various approaches will be implemented in a region, which could in turn be interlinked.

Examples of this can also be seen in some current projects. For example, the Jura project described above (interlinked systems) also contains elements of a common platform, which, in turn, is more consistent with the third option (single systems).

By contrast, although the mBridge project is based on a common platform, it also includes the possibility of linking this platform to other CBDC systems or other platforms. This, too, entails switching between interlinked and single systems. Future interoperability models may include different elements of each option in order to meet the needs of each currency area.

Potential and challenges for the cross-border use of central bank digital currency

All options could be an improvement over the current correspondent banking system

Compared with the current correspondent banking system, all three options promise significant improvements. In theory, interlinking CBDC systems may lead to faster, cheaper and more transparent cross-border payments. Depending on the design of the respective CBDC, this could also give additional user groups within the general public access to cross-border payments. At the same time, the degree of improvement depends on the version of the multilateral cooperation model that is chosen. The overview on p. 73 summarises the potential that each of the options for interoperable CBDC offer compared with the current correspondent banking system.

The degree of interoperability and potential efficiency gains will increase, whether in compatible, interlinked or single systems. However, as the degree of interoperability rises, so too will the complexity of the systems and thus the difficulty of implementing them. This will hold even if the new CBDC systems are only designed as compatible systems (as in the first option). It would need to be clarified, for example, which standards (e.g. messaging standards or standards for the transmission of data for anti-money laundering purposes) in payment processing are to be migrated from the existing systems and which ones are to be abandoned in favour of new, internationally compatible standards. The introduction and implementation of these international standards could pose major challenges for system users and would entail considerable costs. In addition, divergent national interests or different perspectives may hinder closer international cooperation and significantly delay work on the common standards or even bring it to a halt.

The degree of interoperability may also increase efficiency gains, challenges and risks

To a certain extent, the in-depth international cooperation required for the interlinked and single systems is associated with ceding autonomy in favour of common governance structures, which represents an additional obstacle to linking payment systems.[47] This hurdle can be circumvented or at least mitigated by factoring in at an early stage the cross-border use of CBDC systems into the development of new CBDC systems, before their development becomes too divergent in different jurisdictions.

In-depth international cooperation can restrict each country's autonomy

Another obstacle could be the relatively high investment costs for new systems, which might be incurred in addition to the ongoing costs of the current systems. However, elements of existing systems could also be reused, possibly after modification. In this respect, too, it is probably advisable to incorporate the thinking behind the development and operation of a common platform into a country's own project activities at an early stage, as it would become

---

Potential improvements resulting from alternative approaches to interoperable CBDC systems

Frictions in the current correspondent banking system	Potential improvements		
	Compatible systems	Interlinked systems	Single system
High operational costs and (settlement) risks due to multiple bilateral account relationships and balances	Possible reduction in number of business relationships could reduce costs	Common clearing mechanism and settlement in real time could reduce costs and risks	Final settlement in real time and, where applicable, using liquidity-saving mechanisms could reduce costs and (settlement) risks
Different operating hours	Same operating hours if operating 24/7		
Different communication standards	Compatible communication standards can reduce data loss	Harmonised communication standards more or less eliminate data loss	Single communication standard eliminates data loss
Limited transparency on exchange rates and fees	Common calculation of exchange rates could increase transparency	High transparency if common mechanisms, e. g. for currency exchange, are used	
Limited transparency on status of transactions	Transparency depends on the degree of compatibility	High transparency if final settlement is in real time	
Restricted access	Potentially enhanced access to cross-border payments depending on CBDC's access model

Deutsche Bundesbank

more unlikely to achieve such a platform once national CBDC systems have already been introduced across the board.

Different legal and regulatory frameworks can make interoperability more difficult

Moreover, differences in legislation will be a major impediment to the cross-border interoperability of new payment systems. There are differences between countries not only in terms of anti-money laundering and combating the financing of terrorism (AML/CFT), but also regarding the rules governing risk management, cyber security and the handling of personal data. International harmonisation of legal frameworks could have a significant impact on national legal systems that is politically either difficult or impossible to deliver and which is also not offset by the prospect of more efficient cross-border payments.

Spillover effects can create risks through stronger interconnectedness

Another critical factor when setting up interoperable infrastructures is the close interconnectedness between systems in different economic areas. Facilitated by tight integration be-

tween system users, for example, the effects of localised crises in individual economic segments or of participant defaults could spread globally (spillover effects). Faster transaction processing due to closer links or integration is also associated with higher operational risk. As a general rule, the decision regarding the desired degree of interoperability therefore always requires a detailed risk analysis.

Last but not least, greater cooperation always involves an increase in dependencies, which may also have political implications. For example, when using a single system, clear and binding rules for contingency procedures are required, which may lead to the mandatory exclusion of participants from the system in an emergency. Potential conflict could also arise when implementing financial sanctions of various types if they are assessed and implemented differently by the cooperating countries.

Geopolitical aspects need to be considered

■ Outlook and conclusion

CBDC will likely come too late to make a significant contribution to achieving the G20 objectives …

The work initiated by the G20 countries aims to significantly improve the efficiency of cross-border payments, which would require considerable efforts in a relatively short period of time. The corresponding measures should address as many of the weaknesses identified by the G20 countries as possible. In particular, purely technical approaches will not have a lasting impact unless they are accompanied at the same time by a globally consistent implementation of the relevant legal regulations and an improvement in the exchange of information.

The specific objectives that have been formulated so far are supposed to be achieved by 2027. If this timetable is kept, CBDC is unlikely to make any material contribution, as most CBDC projects are at a very early stage and will not be able to unfold much of their potential in cross-border payments during this period. In this respect, it will also be necessary to place a high priority on exploring other private sector approaches, such as the linking of real-time retail payment systems. In recent years, many countries have invested in setting up such payment systems, often based on international standards. In countries with strong political and economic integration, the use of common technical infrastructures for the settlement of cross-currency payments in real time could also be considered outside of CBDC. Such an approach is currently being investigated by the Eurosystem in its efforts to improve TARGET Instant Payment Settlement.[48]

… but it is still worth unlocking the cross-border potential of CBDC

Nevertheless, CBDC will offer the opportunity to increase the speed of settlement of cross-border payments in the medium term, to reduce transaction costs and to intensify competition in international payments. CBDC systems will be designed to provide easy access to CBDC and are likely to increase financial inclusion in many countries, thereby broadening the scope for participation in payment transactions. CBDCs could also unfold their potential in cross-border payments in conjunction with other technologies. For example, linked eID ecosystems could reduce frictions with regard to compliance with financial sanctions as well as AML/CFT measures.

Multilateral cooperation preferable to a unilateral approach

A multilateral approach thus offers the best chance for CBDC to help comprehensively reduce the frictions currently constraining cross-border payments. Various central banks would collaborate in this endeavour: they would issue CBDC, which would held primarily in their own currency area but would allow cross-border payments through interoperability with other CBDC systems. This seems more advantageous than the option of individual central banks making their CBDC usable for cross-border payments unilaterally. Moreover, such an approach would not resolve existing frictions across national borders. If central banks were to even design their own CBDC in such a way that large amounts of it could be held abroad, this would harbour a number of economic risks – not least for themselves. And ultimately, such an approach could be seen as an attempt to create monetary policy or technological dependencies.

Costs of coordination make a globally uniform solution unrealistic

By contrast, were individual central banks to cooperate with each other, the question arises as to how CBDCs should be made interoperable. Any efficiency gains from a higher degree of integration generally come with higher coordination costs. Moreover, a growing degree of integration always implies the ceding of sovereignty, which means that efficiency gains must be weighed against other policy objectives. For example, a single, common worldwide CBDC platform involving a large number of currency areas from the outset is difficult to imagine at this juncture.

However, the combination of various, possibly hybrid approaches could be a more viable option. A high degree of interoperability is likely to be achievable among currency areas that are

---

48 See European Central Bank (2021).

A combination of hybrid approaches could provide the necessary flexibility

closely linked economically and politically, where the willingness to coordinate and compromise is comparatively high and the potential for conflict is limited. Regionally highly integrated systems of this kind could then be made compatible with one another or be interlinked.

Ultimately, this would cover a large number of currency areas without having to enter into a multitude of bilateral cooperation agreements. That said, it remains crucial that interoperability has to be taken into account from the outset when designing CBDC.

Government debt in the euro area: developments in creditor structure

Euro area government debt amounted to 96% of gross domestic product (GDP) at last count. This article describes how creditor structure has evolved in recent years. The focus is on the euro area as a whole and on the four largest Member States, Germany, France, Italy and Spain.

Creditor structure has shifted significantly since 2015 as a result of the Eurosystem's asset purchases. By the end of 2021, the European Central Bank (ECB) and the national central banks had bought government debt in a magnitude of 30% of euro area GDP. Meanwhile, the volume of debt held by other creditors fell. In relation to GDP it was consequently also lower than before the financial and economic crisis. Indebtedness to euro area banks and non-euro area creditors, in particular, has been on the decline since then.

In the large Member States, the respective national central banks, especially, acquired government bonds. As in the euro area as a whole, this was accompanied by a simultaneous decline in the weight of domestic banks and foreign creditors. Overall, government interest payments (including any risk premia) largely flow to domestic recipients, with a good portion going to the national central banks. Profit distributions by central banks mean that interest payments ultimately flow back to the government. De facto, the government thus pays the short-term, risk-free deposit rate for these bonds rather than the bond rate. This channel renders public finances more sensitive to changes in central bank interest rates. Meanwhile, the remaining bonds are less sensitive to interest rates because the residual maturities of government bonds have lengthened in recent years.

Commercial banks are the second-largest creditor sector in the euro area after central banks. Their weight as creditors has developed differently in the individual Member States. Compared with the period before the financial and economic crisis, banks in Germany currently hold less national government debt (securities and loans, as a percentage of GDP). In France, holdings were stable, overall, during this period. In Spain and Italy, meanwhile, they increased significantly on balance. A similar development is seen for the ratio of home-country government debt held by banks as a percentage of national banking systems' own funds. The nexus between national banking systems and their home country harbours risks to financial stability. Reducing these risks seems particularly important if risk sharing in the European banking union is to be stepped up. Reducing the regulatory privileges that government debt enjoys on bank balance sheets would reduce these risks. This proposal has, however, found no political majority to date.

▪ Introduction

Focus on creditor structure of government debt

This article focuses on the creditor structure of euro area government debt. A brief outline will also be given of the structure of debt instruments. The euro area is analysed as a whole and, by way of example, the four largest euro area countries – Germany, France, Italy and Spain. Among the creditor groups, the Eurosystem (the ECB and the national central banks) and the national banking systems especially are looked at in greater detail. These groups have played a key role in shaping developments in recent years.

Various data sources are used

Different data sources are used in the various sections of the article. In some cases, their definitions differ, and the data are also obtained from different sources. The data sources, their statistical definition and the associated ambiguities are explained on pp. 82 and 83. The main data base used for creditor structure has been available since the middle of the last decade.

▌ Government debt: size, instruments and residual maturity

High debt ratio in the euro area

At the end of 2021, the total government debt of all euro area countries amounted to 96% of the euro area's GDP. From a starting point of 70% at the end of 2008, the debt ratio had risen sharply during the financial and sovereign debt crisis. After declining moderately until 2019, the ratio jumped back up during the coronavirus pandemic. It reached 97% at the end of 2020, its highest level since the start of monetary union (see the upper chart on p. 79).[1]

Long-term debt dominates

Debt instruments predominantly constitute medium to long-term liabilities. They have become even more significant over time:[2] the percentage of liabilities with a maturity of more than one year in total debt rose from 85% at the end of 2008 to almost 90% at the end of 2021. The list is topped by debt securities (especially bonds), which are generally marketable. They

have significantly greater weight than loans, which banks, in particular, issue to governments. State liabilities from currency and deposits represent only a small share of government debt, at around 3%. These are liabilities related to government coin issuance or deposits made with the government.

Large differences in national debt ratios

The individual Member States' debt ratios vary widely (see the lower chart on p. 79). Figures range from 18% in Estonia to 193% in Greece. The structure is mostly dominated by long-term debt in the form of securities. The main exceptions are those countries that still have significant levels of long-term assistance loans (Greece, Portugal and Cyprus).[3] The assistance loans were granted in connection with the sovereign debt crisis.

Increase in bonds' average residual maturity

The average residual maturity of government securities debt has increased in recent years (see the chart on p. 80 for the four large Member States). Changes in interest rates therefore have a smaller impact on government finances, as interest payments are, for the most part, fixed for longer periods.[4] After the onset of the financial and economic crisis, residual maturities had mostly fallen markedly.

---

1 In addition, the EU level took out debt for the Support to mitigate Unemployment Risks in an Emergency (SURE) programme and the Next Generation EU (NGEU) programme. The EU Member States ultimately shoulder the interest and principal payments for this debt. Where these funds are used to finance grants to the EU Member States, they are not included in national debt levels. For example, grants totalling €390 billion (in 2018 prices) are planned under the NGEU programme. This is equivalent to roughly 3% of the EU's GDP in 2021. For more detailed information, see Deutsche Bundesbank (2020, 2022a).
2 Classification into short-term and long-term liabilities according to Eurostat's Government Finance Statistics: short-term liabilities with original maturities of up to one year, long-term liabilities with original maturities of more than one year or without details on maturity.
3 Greece was also issued with bilateral assistance loans by the other euro area Member States (Greek Loan Facility). In addition, the Member States most affected by the sovereign debt crisis received financial assistance from the European Commission (under the European Financial Stabilisation Mechanism, EFSM) and the International Monetary Fund.
4 In individual cases, variable interest rates may also have been agreed for long maturities. On the other hand, debtors can also use derivatives to secure fixed interest rates beyond the residual maturity.

Government debt: structure of creditors[5]

A look at the euro area as a whole

In the middle of the last decade, euro area banks and foreign creditors represented the largest creditor groups

In the middle of the last decade, almost one-third of euro area countries' government debt was held outside of the euro area (see the chart on p. 81). Looking at the domestic euro area sectors, monetary financial institutions dominated (hereinafter referred to as "banks", excluding central banks). They also held almost one-third of total debt. They were followed by insurance corporations and pension funds (13%) as well as other financial institutions such as investment funds (9%). Looking at the euro area as a whole, households, international institutions, the Eurosystem and non-financial corporations played only a minor role as creditors.

From 2015, large-scale government bond purchases by the Eurosystem central banks

Creditor structure has shifted considerably since then, mainly as a result of the Eurosystem's large-scale government bond purchases.[6] At the end of 2021, the Eurosystem's holdings of government bonds issued by Member States amounted to around €3.6 trillion, or 30% of euro area GDP.[7] The Eurosystem's holdings were therefore significantly larger than the increase in Member States' debt since the end of 2014, which amounted to €2.3 trillion.[8] Since

---

5 The data used have been consistently available since the fourth quarter of 2013.

6 The Eurosystem purchased public sector bonds on a large scale through the public sector purchase programme (PSPP) from March 2015 and the pandemic emergency purchase programme (PEPP) from March 2020. National central banks predominantly acquired bonds issued by their own Member State. The ECB bought around 10% of the purchase volume. Purchases by the national central banks are not subject to risk sharing, and the national central bank receives the interest income. The ECB purchases are subject to risk sharing. For information on the rationale behind and the design of the various programmes, see the Official Journal of the European Union L 39 (2020a) and the Official Journal of the European Union L 91 (2020b).

7 This does not include bonds purchased by supranational institutions. Including these "supras", holdings total around €4 trillion or 33% of euro area GDP. Holdings of government bonds that the Eurosystem central banks acquired in line with the Agreement on Net Financial Assets (ANFA) are likewise not included.

the onset of the financial and economic crisis, Eurosystem holdings account for around three-quarters of the rise in debt (+€5.0 trillion since the end of 2008). As a percentage of GDP, debt not held by the Eurosystem is lower than before the financial and economic crisis.

Eurosystem largest creditor

The Eurosystem was thus by far the largest creditor sector at the end of 2021 (see the upper chart on p. 81). For almost all other sectors, the holdings of government debt fell in absolute terms and as a percentage of GDP as compared with the end of 2014. Insurance corporations and pension funds are the only exception. The decline in debt to foreign creditors (non-euro area) was particularly significant, followed by banks and other financial institutions within the euro area.

A closer look at Germany, France, Italy and Spain

Different creditor structures in the four large Member States

A more detailed description of developments in the four large Member States Germany, France, Italy and Spain is given below. Developments in their government debt ratios and creditor structures have diverged. They also differed significantly at the end of 2021.

Differences in the level and evolution of debt ratios

The debt ratios in the four countries rose considerably from different levels following the onset of the financial and economic crisis (see the lower chart on p. 81). By the time the coronavirus pandemic broke out in 2020, Germany's debt ratio was well below its level of end-2008 again. During the same period, the debt ratio in France continued to rise moderately, whereas it stagnated at the higher level in Spain and Italy. During the coronavirus pandemic in 2020 and 2021, all countries experienced a renewed sharp rise in their debt ratios. The German debt ratio was only 4 percentage points higher at the end of 2021 than at the end of 2008. In France, it had risen by 44 percentage points, in Italy by 45 percentage points and in Spain it was 79 percentage points higher (starting from a moderate level).

Prior to 2015, the main holders of government debt were foreign creditors in Germany and France and domestic banks in Italy and Spain

The table on p. 85 contains detailed information on the creditor structure of the four countries. It shows the holdings of the creditor groups both in relation to total debt and in relation to national GDP. In Germany and France, foreign creditors (in this case, creditors from outside the respective Member State excluding the Eurosystem central banks) held just under 60% of government debt in 2014. Domestic banks were the second-largest creditor group in Germany, holding around one-quarter of government debt, while the figure for France was around one-fifth. In Italy, meanwhile, external debt stood at just over one-third and in Spain at just under 40% of government debt. At close to one-third, debt to domestic banks was only moderately lower in these countries.

Creditor structure has shifted significantly since the start of the asset purchase programmes

In 2015, the large-scale asset purchases by the Eurosystem central banks started and altered creditor structures considerably (see the table on p. 85, chart on p. 84). At the end of 2021, asset holdings under the purchase programmes amounted to 39% in Germany, 27% in France, 25% in Italy and 32% in Spain, as a percentage of the respective government debt. In Germany and France, meanwhile, the shares held by foreign creditors (excluding the ECB, which is included under the Eurosystem in this presenta-

Deutsche Bundesbank

tion), in particular, fell. They previously held an especially large percentage. In Italy, the shares of all other creditor groups fell relatively broadly. In Spain, the percentage held by domestic banks, in particular, dropped.

Eurosystem holdings (as a percentage of the respective GDP) range between 27% for Germany and 38% for Italy and Spain

The macroeconomic relevance can be seen in holdings relative to national GDP. At the end of 2021, the Eurosystem's (Bundesbank's and ECB's) holdings of German government debt acquired for monetary policy purposes amounted to 27% of (German) GDP. The equivalent figure for France was 31%, while it was 38% for both Italy and Spain.[9] Everywhere except for France, the holdings accumulated by

the Eurosystem exceeded the increase in debt over the same period.[10] For the pandemic years 2020 and 2021, the build-up of Eurosystem holdings in the four Member States was roughly in line with the increase in debt.[11]

The creditor structure can be used to determine the extent to which government interest expenditure remains within a country or goes beyond its borders. This also applies to the risk premia that this expenditure contains. Debt held by foreign creditors as a percentage of GDP gives some indication of the flow of inter-

Interest payments pass through to foreign creditors to only a limited extent

9 The restrictions regarding the interpretation and presentation of the Eurosystem's share mentioned on p. 82 apply. The figures diverge because the purchases under the PSPP and PEPP are based on the Eurosystem's capital key. This is made up of the respective share of a Member State in the total population (currently for 2018) and euro area GDP (currently the average for 2013-17), whereby both have equal weighting. In 2021, the ratio of capital key to GDP share was 90% for Germany, 102% for France, 119% for Italy and 120% for Spain.

10 At the end of 2021, Germany's holdings of government bonds amounted to around €970 billion, whereas its debt level rose by €270 billion between 2014 and 2021. For France, the figures are around €760 billion and €770 billion respectively, for Italy around €670 billion and €470 billion respectively, and for Spain around €460 billion and €340 billion respectively.

11 For Germany and Italy, the ratio between the increase in Eurosystem holdings and the rise in debt was 109% over this period, for Spain it was 100%, and for France it was 82%.

Information on the data and their statistical definition

Various data sources were combined in this article so as to provide the most comprehensive picture possible. The data are not fully compatible in some cases, nor are they uniformly defined, leading to ambiguities in some places. However, this is unlikely to have a significant impact on the fundamental developments presented. The last date for which the data used are jointly available is the end of 2021.

Data on the volume and instrument structure of government debt are taken from Eurostat's Government Finance Statistics (GFS). This is general government debt (according to the national accounts) at nominal values, which is also referred to as the Maastricht debt level.[1]

Data on the creditor structure of securities are taken mainly from the Securities Holdings Statistics (SHS) and the Securities Holdings Statistics by Sector (SHSS) of the European Central Bank (ECB). These comprise the bond holdings of the aggregate sectors for the euro area as a whole and for individual Member States, excluding central banks in each case. Consistent data are available for these from the fourth quarter of 2013. All figures are nominal.

These securities data are supplemented by data on the creditor structure of banks' credit claims (nominal values), taken from the ECB's balance sheet statistics. No separate information on holders is available for credit claims on general government not held by banks or government liabilities from currency and deposits (6% and 1%, respectively, of total debt in the euro area). These categories are reported under "Other".

These data are supplemented by data from the European Stability Mechanism (ESM) on the outstanding financial assistance provided under the European Financial Stability facility (EFSF) and the ESM (nominal values).

Data on the government bonds of Member States held by the Eurosystem are taken from publications by the ECB and the national central banks. The holdings reported include all purchases of public sector bonds issued by Member States under the monetary policy asset purchase programmes (purchases of bonds issued by supranational institutions are not taken into account in this article). However, in addition to government bonds issued by Member States, the Eurosystem also purchases bonds issued by national development banks and other national public undertakings. The latter are not usually included in national government debt. In this respect, the Eurosystem's actual holdings of government debt (as defined by the GFS) are likely to be lower than reported here (this is probably the case for Germany, at least).

Moreover, the holdings of the Eurosystem are measured differently to the other figures reported in this article. For example, only holdings under the Securities Markets Programme are published at nominal values. By contrast, holdings under the significantly larger purchase programmes from 2015 onwards are reported according to balance sheet data. Wherever the Eurosystem has purchased securities at prices above the nominal value, its share is thus overstated (this is likely to have been the case in most instances).

However, the share of Eurosystem central banks as creditors of government bonds is underreported in a different context. Specifically, the Eurosystem's reported shares do not include government bonds purchased by national central banks for their own portfolios outside the monetary policy asset purchase programmes (based on the Agree-

---

1 See Deutsche Bundesbank (2018).

ment on Net Financial Assets (ANFA)).[2] Data on the holdings of domestic government bonds that these contain are not published.

Government bonds held abroad are not explicitly recorded in the creditor structure statistics, which are the main source used here. This is because securities depositories from non-euro area countries are not subject to reporting requirements. For this reason, the category of government debt held abroad was calculated and reported as a residual figure in this article. This is the result of the difference between the outstanding national debt securities according to the GFS and the sum of the holdings reported in the SHS and SHSS holdings statistics as well as the holdings of the Eurosystem (again, excluding supranational bonds).[3] The aforementioned ambiguities stemming from the different statistical definitions of the data (in particular with regard to the Eurosystem's holdings) affect this residual.

In this respect, Germany's external debt, for example, is likely to be underestimated whilst Italy's is overestimated. There is one further aspect to bear in mind when interpreting and differentiating between the domestic country and foreign countries. Although the reported statistics distinguish domestic holdings of government bonds from holdings abroad, this does not necessarily mean they are held by domestic or foreign creditors in each case. Foreign creditors can also hold government bonds in domestic safe custody accounts, and vice versa.

---

2 ANFA governs the extent to which the national central banks are allowed to invest beyond monetary policy purposes. See Deutsche Bundesbank (2016).
3 In order to provide financial assistance to Member States that were hit especially hard by the financial and debt crisis, euro area countries jointly borrowed through the EFSF. In the figures reported for individual Member States in this article, this share was allocated to external debt.

est to other countries. To examine this aspect, the analysis of Eurosystem bond holdings conducted so far has to be expanded to include a distinction between domestic and foreign holdings. From a national perspective, the ECB's holdings are held largely by foreign creditors. This is because they are subject to risk sharing and, therefore, the bulk of the interest paid on the ECB's holdings goes to other countries.[12] By contrast, all interest payments on national central banks' holdings remain within their respective home countries. Defined in this way, debt held by foreign creditors in Germany amounted to 23% of German GDP. The equivalent figure for France was 49%, 43% for Italy and 44% for Spain.

National central banks have sizeable claims on home countries

At present, a large share of the interest expenditure remaining inside respective euro area countries is being channelled to their national central banks, mainly owing to the national central banks' holdings of bonds issued by their home countries. In addition, there are the hold-

ings of bonds issued by the home countries and purchased by the Eurosystem with risk sharing (see the table on p. 86). This is because the interest paid on these bonds is distributed to all national central banks in line with the capital key. At the end of 2021, holdings calculated in this manner as a percentage of national GDP stood at 25% (Bundesbank holdings) for Germany, 28% for France, 34% for

---

12 The Eurosystem agreed on full risk sharing for purchases under the Securities Markets Programme (SMP). For purchases under the PSPP and PEPP, it agreed that 20% of purchases would be subject to risk sharing. These are the ECB's purchases of government bonds and bonds issued by development banks and other public undertakings, as well as purchases by the national central banks of bonds issued by supranational institutions (10% in each instance). Interest income on holdings subject to risk sharing is distributed between the national central banks in accordance with the Eurosystem's capital key. 80% of purchases under the PSPP and PEPP are excluded from risk sharing. These are purchases by the national central banks of securities issued by regional and local governments, development banks and other public undertakings within the national central banks' jurisdiction.

Deutsche Bundesbank

Italy and 35% for Spain.[13] In addition, the Eurosystem central banks can (under ANFA) hold government bonds in portfolios for non-monetary policy purposes. The Bundesbank does not make use of this option. The relevant ANFA balance sheet items of the Banque de France total around 2% of national GDP, while those for the Banca d'Italia amount to 7% and those for the Banco de España 2%.[14] The share of government bonds issued by national central banks' home countries within these aggregate items is not published, but is likely to be substantial in some cases.

Eurosystem bond purchases affect debt burden on government finances …

Eurosystem government bond holdings influence the way in which debt puts pressure on government finances and in which interest rate changes affect government finances.[15] Put in highly simplified terms, national central banks' bond purchases convert the rate of interest paid on government debt from the country-specific medium to longer-term bond rates (including any risk premia) to a variable interest

[13] For these figures, bonds purchased by the Eurosystem with risk sharing were allocated to the respective Member States according to the capital key. These are SMP holdings and the ECB's country-specific purchases under the PSPP and the PEPP, each excluding holdings of bonds issued by supranational institutions. In addition, central banks also receive income from holdings of non-domestic securities and bonds issued by supranational institutions for purchases of which risk sharing has been agreed. As a percentage of national GDP, the Eurosystem's holdings of this nature amounted to around 5% for the Bundesbank, 6% for the Banque de France and 7% for the Banca d'Italia and the Banco de España.

[14] The data were taken from the balance sheets of the national central banks for the 2021 financial year. These figures concern all relevant euro-denominated investments, not just national government bonds. The table on p. 86 shows, in particular, balance sheet items 7.2. (Other securities not held for monetary policy purposes) and 11.3 (Other financial assets). Relevant supplementary information in the annual reports has been taken into account. See Banca d'Italia (2022), Banco de España (2022), Banque de France (2022) and Deutsche Bundesbank (2022b). The Bundesbank has no holdings in this context. The Banque de France has holdings of €43.4 billion and the Banco de España holdings of €28.8 billion. In its annual report on other investment in euro area government bonds, the Banca d'Italia reported a figure of €125.1 billion.

[15] For more details on the mechanism outlined here in a simplified manner as well as additional influences and features, see Deutsche Bundesbank (2021a).

Deutsche Bundesbank

rate at the monetary policy (risk-free) rate. This is due to the fact that interest payments on the purchased government bonds go to the national central banks. As bond purchases grew, so did commercial banks' deposits at central banks. In turn, the national central banks pay interest on these (now 0%, previously at a negative deposit facility rate). The difference between income from bond holdings and expenditure on the deposit facility affects central bank profit. As soon as it is distributed, it has an impact on government finances.[16] In this respect, the balance sheet link between central banks and government finances means that interest rates on bonds (including risk premia)

flow back to the Member States, which effectively pay the short-term deposit rate.

In terms of interest rate risk to government finances, the described lengthening of the residual maturities for government debt should therefore be interpreted with caution. Where central banks engage in maturity transformation via their balance sheets, this increases the sensitivity of government finances to short-term changes in central bank interest rates. This counterbalances the longer residual maturities.

… and sensitivity to short-term changes in central bank interest rates

16 The timeframe can be influenced by provisions and loss carryforwards.

Deutsche Bundesbank

Bond purchases are reflected in central bank profits

The varying interest rates on holdings of government bonds issued by the home country are reflected in the national central banks' balance sheets. Although other effects also play a role (including changes in provisions and reserves), this can be seen, for example, in last year's annual accounts of the national central banks of the four large Member States. While the Bundesbank did not distribute any profit to the government in 2022 (2021 financial year), transfers (including payments of profit-related taxes) amounted to 0.3% of GDP in France and Spain and to 0.8% of GDP in Italy in the same year.

Government debt held by the national banking sector

The domestic banking system is the second-largest creditor sector in the euro area after central banks. The banking system is of particular importance in terms of financial stability.

The sovereign debt crisis showed that problems with government finances and in the banking system can quickly be mutually reinforcing and pose a threat to financial stability. For example, government solvency risks feed through various transmission channels to affect the credit quality and funding options of banks. At the same time, distress in the banking system can trigger or exacerbate sovereign debt crises. In view of this, changes in national banking sectors' claims on their home countries are of particular interest.

As major lenders to government, banks play a particularly important role in safeguarding financial stability

A look at the euro area as a whole

At the end of 2021, the aggregate euro area banking sector (euro area monetary financial institutions excluding central banks) held claims on Member States amounting to 21% of GDP (see the chart on p. 87). These were mainly claims on the respective home country. These

Euro area banks mainly hold claims on their home countries

Deutsche Bundesbank

Banks' claims on home countries as they were prior to financial and economic crisis

play a crucial role in the national sovereign-bank nexus.

At the end of 2021, banks' claims on their home countries were back at a level similar to the one recorded at the end of 2008 (17% of euro area GDP in each case; see the chart above).[17] Over the course of the financial and sovereign debt crisis, banks had considerably expanded their holdings of these claims (particularly government bonds). However, they reduced them again when the Eurosystem launched its large-scale asset purchase programmes.

Ratio of government bond holdings to own funds somewhat reduced

Looking at claims in relation to the own funds of domestic banks, the picture is similar. These funds are ultimately the buffer that banks can use to absorb any losses. Comparing claims on the home countries to the own funds of the domestic banking system, this figure has fallen slightly, from 90% prior to the financial and economic crisis to just under 80% (see the lower chart on p. 88).[18]

A closer look at Germany, France, Italy and Spain

In turn, developments in the four large Member States were very different (see the upper

chart on p. 88). Upon the outbreak of the financial and economic crisis, banks in all Member States increased their claims on their respective home countries. In Germany and France, these claims rose only slightly and remained roughly at the level then reached from 2011 onwards. By contrast, banks domiciled in Spain and Italy considerably expanded their claims on their home countries. Following the launch of the Eurosystem's purchase programmes, banks' claims on their home countries fell in all Member States from 2015 onwards, especially in Spain. In Italy, this trend then reversed starting in early 2018 amid heightened uncertainty surrounding the country's elections and the formation of a new government. In France and Spain, the banking sectors started expanding their holdings of national government bonds again when the coronavirus pandemic broke out. Compared with the situation prior to the financial and economic crisis, it was only in Germany that banks' claims on the home country decreased – in relation to GDP, they went from just under 19% at the end of 2008 to 11% at the end of 2021. At 16% of GDP, the

Differing developments in the four large Member States

17 46% of the claims on home countries are credit claims and 54% are government bonds.
18 Own funds of the domestic banking sector are defined as capital and reserves according to the ECB's balance sheet statistics. These values may differ from bank to bank. They are therefore only a rough, aggregate indicator.

Claims of banks in selected Member States on countries

Deutsche Bundesbank

ratio in France was back on par with the one recorded at the end of 2008. In Spain, it went up from 14% to 23%, whilst in Italy, starting at 24%, it reached a new peak of 38%.[19]

Banking sectors in Spain, but especially Italy, vulnerable to sovereign default risks

Looking at the claims on each home country in relation to the own funds of its domestic banks also reveals a mixed picture (see the chart above).[20] While the ratio for Germany stood at 126% at the end of 2008, it had fallen to 62% by the end of 2021. For France, this figure decreased from 77% to 56% over the same period. By contrast, these ratios increased in Spain and Italy. Following the outbreak of the

financial and economic crisis, they rose from 67% to 110% in Spain and in Italy from 147% to just under 200% at the end of the period under review.

Overall, it is clear that banks are interconnected, sometimes closely, with their home country. Compared with the situation prior to the financial and economic crisis, the link is in some cases even stronger. Banks, therefore, have not all become more resilient to the fiscal risks of their home country. In this respect, financial stability risks remain. Further steps towards broader risk redistribution within the framework of the banking union are currently under discussion. If this should fail to achieve a larger-scale redistribution of fiscal risks, it would be necessary to place a tight limit on the risks for banks arising from government bonds.[21]

Close interconnectedness between banks and their home country continues

Bank sectors of selected Member States: claims on the home country in relation to own funds

%, year-end data

19 Deviations from the table on p. 85 arise from the valuation approach used in the balance sheet statistics, which report bond holdings at book values. By contrast, they are reported at nominal values in the SHSS holdings statistics. Bonds accounted for 37% of domestic banks' total claims on the home country for Germany, 46% for France, 61% for Italy and 71% for Spain.
20 The situation in which individual banks find themselves can vary considerably.
21 In addition, risks in banks' balance sheets arising from legacy debt, such as the various losses arising from non-performing loans, would have to be sufficiently mitigated in advance. The current resolution regime for banks also needs to be reformed so that, wherever possible, no public funds will be used to bail out banks in future. For more details, see Deutsche Bundesbank (2021b).

Reducing the regulatory privileges that government debt enjoys on bank balance sheets would go some way to achieving this, but so far this has lacked a political majority.

euro banknotes put into circulation by the Bundesbank in accordance with the accounting regime chosen by the Eurosystem (see also footnote 2 on banknote circulation in Table III.2). The volume of currency actually put into circulation by the Bundesbank can be calculated by adding to this total the item "Intra-Eurosystem liability/claim related to banknote issue" (see "Other liability items"). **5** Excluding central governments' deposits. **6** In Germany, only savings deposits.

* Monetary financial institutions (MFIs) comprise banks (including building and loan associations), money market funds, and the European Central Bank and national central banks (the Eurosystem). **1** Source: ECB. **2** In Germany, only savings deposits. **3** Excluding holdings of MFIs; for the German contribution, excluding German MFIs' portfolios of securities issued by MFIs in the euro area. **4** In Germany, bank debt securities with maturities of up to one year are classed as money market paper.

5 Excluding liabilities arising from securities issued. **6** After deduction of inter-MFI participations. **7** The German contributions to the Eurosystem's monetary aggregates should on no account be interpreted as national monetary aggregates and are therefore not comparable with the erstwhile German money stocks M1, M2 or M3. **8** Including DEM banknotes still in circulation (see also footnote 4 on p. 10•). **9** For the German contribution, the difference between the volume of euro banknotes

Discrepancies may arise from rounding. ***** The banking system's liquidity position is defined as the current account holdings in euro of euro area credit institutions with the Eurosystem. Amounts are derived from the consolidated financial statement of the Eurosystem and the financial statement of the Bundesbank. **1** Figures are daily averages for the reserve maintenance period ending in the month indicated. Following the changeover in the frequency of Governing Council monetary policy meetings to a six-week cycle, a reserve maintenance period no longer ends in every month. No figures are available in such cases. **2** Source: ECB. **3** Includes liquidity provided under the Eurosystem's asset purchase programmes. **4** From August 2009 includes liquidity absorbed as a result of the Eurosystem's foreign exchange swap operations. **5** From 2002 euro banknotes and other banknotes which have been issued by the national central banks of the Eurosystem and which are still in circulation. In accordance with the accounting procedure chosen by the Eurosystem for the issue of euro banknotes, a share of 8% of the total value of the euro banknotes in circulation is

allocated to the ECB on a monthly basis. The counterpart of this adjustment is shown under "Other factors". The remaining 92% of the value of the euro banknotes in circulation is allocated, likewise on a monthly basis, to the NCBs, with each NCB showing in its balance sheet the share of the euro banknotes issued corresponding to its paid-up share in the ECB's capital. The difference between the value of the euro banknotes allocated to an NCB and the value of the euro banknotes which that NCB has put into circulation is likewise shown under "Other factors". From 2003 euro banknotes only. **6** Remaining items in the consolidated financial statement of the Eurosystem and the financial statement of the Bundesbank. **7** Equal to the difference between the sum of liquidity-pro viding factors and the sum of liquidity-absorbing factors. **8** Calculated as the sum of the "Deposit facility", "Banknotes in circulation" and "Credit institutions' current account balances".

III. Consolidated financial statement of the Eurosystem

1. Assets *

€ billion

As at reporting date	Total assets	Gold and gold receivables	Claims on non-euro area residents denominated in foreign currency			Claims on euro area residents denominated in foreign currency	Claims on non-euro area residents denominated in euro		
			Total	Receivables from the IMF	Balances with banks, security investments, external loans and other external assets		Total	Balances with banks, security investments and loans	Claims arising from the credit facility under ERM II

* The consolidated financial statement of the Eurosystem comprises the financial statement of the European Central Bank (ECB) and the financial statements of the national central banks of the euro area Member States (NCBs). The balance sheet items for foreign currency, securities, gold and financial instruments are valued at market rates at the end of the quarrter. **1** In accordance with the accounting procedure chosen by the Eurosystem for the issue of euro banknotes, a share of 8% of the total value of the euro banknotes in circulation is allocated to the ECB on a monthy basis. The counterpart of this adjustment is disclosed as an "Intra-Eurosystem liability related to

III. Consolidated financial statement of the Eurosystem

euro banknote issue". The remaining 92% of the value of the euro banknotes in circulation is allocated, likewise on an monthly basis, to the NCBs, with each NCB showing in its balance sheet the share of the euro banknotes issued corresponding to its paid-up share in the ECB's capital. The difference between the value of the euro banknotes allocated to the NCB according to the aforementioned accounting procedure and the value of euro banknotes put into circulation is also disclosed as an "Intra-Eurosystem claim/liability related to banknote issue". **2** For the Deutsche Bundesbank: including DEM banknotes still in circulation. **3** Source: ECB.

IV. Banks

1. Assets and liabilities of monetary financial institutions (excluding the Deutsche Bundesbank) in Germany *

* This table serves to supplement the "Overall monetary survey" in Section II. Unlike the other tables in Section IV, this table includes - in addition to the figures reported by banks (including building and loan associations) - data from money market funds. **1** See footnote 1 in Table IV.2. **2** Excluding deposits of central governments.

IV. Banks

in other Member States [2]				Deposits of central governments		Liabilities arising from repos with non-banks in the euro area	Money market fund shares issued [3]	Debt securities issued [3]		Liabilities to non-euro area residents	Capital and reserves	Other Liabilities [1]	Period
With agreed maturities		At agreed notice											
Total	of which: up to 2 years	Total	of which: up to 3 months	Total	of which: domestic central governments			Total	of which: with maturities of up to 2 years [3]

* Assets and liabilities of monetary financial institutions (MFIs) in Germany. The assets and liabilities of foreign branches, of money market funds (which are also classified as MFIs) and of the Bundesbank are not included. For the definitions of the respective items, see the footnotes to Table IV.3. **1** Owing to the Act Modernising Accounting Law (Gesetz zur Modernisierung des Bilanzrechts) of 25 May 2009, derivative financial instruments in the trading portfolio (trading portfolio derivatives) within the meaning of Section 340e (3) sentence 1 of the German Commercial Code (Handelsgesetzbuch) read in conjunction with Section 35 (1) number 1a of the Credit Institution Accounting Regulation (Verordnung über die Rechnungslegung der Kreditinstitute) are classified under "Other assets and liabilities" as of the December 2010 reporting date. Trading portfolio derivatives are listed separately in the Statistical Series Banking statistics, in Tables I.1 to I.3. **2** For building and loan associations: including deposits under savings

IV. Banks

Deposits of banks (MFIs)			Deposits of non-banks (non-MFIs)									Bearer debt securities out-standing [5]	Capital including published reserves, partici-pation rights capital, funds for general banking risks	Other liabi-lities [1]	End of month

1 The reserve maintenance period starts on the settlement day of the main refinancing operation immediately following the meeting of the Governing Council of the ECB for which the discussion on the monetary policy stance is scheduled. **2** Article 5 of the Regulation (EU) 2021/378 of the European Central Bank on the application of minimum reserve requirements (excluding liabilities to which a reserve ratio of 0% applies, pursuant to Article 6(1)(a)). **3** Amount after applying the reserve ratio to the reserve base. The reserve ratio for liabilities with agreed maturities of up to two years was 2% between 1 January 1999 and 17 January 2012. Since 18 January 2012, it has stood at 1%. **4** Article 6(2) of the Regulation (EU) 2021/378 of the European Central Bank on the application of minimum reserve requirements. **5** Average credit balances of credit institutions at national central banks. **6** Average credit balances less required reserves after deduction of the lump-sum allowance. **7** Required reserves after deduction of the lump-sum allowance.

* The interest rate statistics gathered on a harmonised basis in the euro area from January 2003 are collected in Germany on a sample basis. The MFI interest rate statistics are based on the interest rates applied by MFIs and the related volumes of euro-denominated deposits and loans to households and non-financial corporations domiciled in the euro area. The household sector comprises individuals (including sole proprietors) and non-profit institutions serving households. Non-financial corporations include all enterprises other than insurance corporations, banks and other financial institutions. The most recent figures are in all cases to be regarded as provisional. Subsequent revisions appearing in the following Monthly Report are not specially marked. Further information on the MFI interest rate statistics can be found on the Bundesbank's website (Statistics/Money and capital markets/Interest rates and yields/Interest rates on deposits and loans). o The statistics on outstanding amounts are collected at the end of the month. 1 The effective interest rates are calculated either as annualised agreed interest rates or as narrowly defined effective rates. Both calculation methods cover all interest payments on deposits and loans but not any other related charges which may occur for enquiries, administration, preparation of the documents, guarantees and credit insurance. 2 Data based on monthly balance sheet statistics. 3 Secured and unsecured loans for home purchase, including building and home improvements; including loans granted by building and loan associations and interim credits as well as transmitted loans granted by the reporting agents in their own name and for their own account. 4 Loans for consumption are defined as loans granted for the purpose of personal use in the consumption of goods and services. 5 For the purpose of these statistics, other loans are loans granted for other purposes such as business, debt consolidation, education, etc. 6 Including overdrafts (see also footnotes 12 to 14 on p. 47).

For footnotes * and 1 to 6, see p. 44•. For footnote x see p. 47•. + For deposits with an agreed maturity and all loans excluding revolving loans and overdrafts, credit card debt: new business covers all new agreements between households or non-financial corporations and the bank. The interest rates are calculated as volume-weighted average rates of all new agreements concluded during the reporting month. For overnight deposits, deposits redeemable at notice, revolving loans and overdrafts, credit card debt: new business is collected in the same way as outstanding amounts for the sake of simplicity. This means that all outstanding deposit and lending business at the end of the month has to be incorporated in the calculation of average rates of interest. 7 Estimated. The volume of new business is extrapolated to form the underlying total using a grossing-up procedure. 8 Including non-financial corporations' deposits; including fidelity and growth premiums. 9 Excluding overdrafts. 10 Annual percentage rate of charge, which contains other related charges which may occur for enquiries, administration, preparation of the documents, guarantees and credit insurance.

For footnotes * and 1 to 6, see p. 44•. For footnotes + and 7 to 10, see p. 45•; **11** For the purposes of the interest rate statistics, a loan is considered to be secured if collateral (amongst others financial collateral, real estate collateral, debt securities) in at least the same value as the loan amount has been posted, pledged or assigned. **12** Including revolving loans which have all the following features: (a) the borrower may use or withdraw the funds to a pre-approved credit limit without giving prior notice to the lender; (b) the amount of available credit can increase and decrease as funds are borrowed and repaid; (c) the loan may be used repeatedly; (d) there is no obligation of regular repayment of funds. **13** Overdrafts are defined as debit balances on current accounts. They include all bank overdrafts regardless of whether they are within or beyond the limits agreed between customers and the bank. **14** Including convenience and extended credit card debt. Convenience credit is defined as the credit granted at an interest rate of 0% in the period between payment transactions effected with the card during one billing cycle and the date at which the debt balances from this specific billing cycle become due. **15** The amount category refers to the single loan transaction considered as new business. **x** Dominated by the business of one or two banks. Therefore, the value cannot be published due to confidentiality.

Sources: The calculations for the insurance sectors are based on supervisory data according to Solvency I and II and for pension funds on IORP supervisory data and own data collections as of 2020 Q1. Until 2019 Q4 these are compiled using Solvency I supervisory data, supplemented by voluntary reports and own calculations. **1** Accounts receivable to monetary financial institutions, including registered bonds, borrowers' note loans and registered Pfandbriefe. For pension funds as of 2020 Q1 fair values, previously book values. **2** Including deposits retained on assumed reinsurance as well as registered bonds, borrowers' note loans and registered Pfandbriefe. For pension funds as of 2020 Q1 fair values, previously book values. **3** Including reinsurance recoverables and claims of pension funds on pension managers. **4** Valuation of listed securities at the corresponding consistent price from the ESCB's securities database. **5** Not including the reinsurance business conducted by primary insurers, which is included there. **6** The term "pension funds" refers to the institutional sector "pension funds" of the European System of Accounts. Pension funds thus comprise company pension schemes and occupational pension schemes for the self-employed. Social security funds are not included. **7** Change in data sources.

Sources: The calculations for the insurance sectors are based on supervisory data according to Solvency I and II and for pension funds on IORP supervisory data and own data collections as of 2020 Q1. Until 2019 Q4 these are compiled using Solvency I supervisory data, supplemented by voluntary reports and own calculations. **1** Including deposits retained on ceded business as well as registered bonds, borrowers' note loans and registered Pfandbriefe. **2** Including claims of pension funds on pension managers and entitlements to non-pension benefits. **3** Technical reserves "life" taking account of transitional measures. Health insurance is also included in the "non-life insurance" sector. **4** Own funds correspond to the sum of "Net worth" and "Shares and other equity". **5** Not including the reinsurance business conducted by primary insurers, which is included there. **6** Valuation at book values. The term "pension funds" refers to the institutional sector "pension funds" of the European System of Accounts. Pension funds thus comprise company pension schemes and occupational pension schemes for the self-employed. Social security funds are not included. **7** Change in data sources.

1 Bearer debt securities with maximum maturities according to the terms of issue of over 4 years. Structured debt securities, debt securities with unscheduled redemption, zero coupon bonds, floating rate notes and bonds not denominated in Euro are not included. Group yields for the various categories of securities are weighted by the amounts outstanding of the debt securities included in the calculation. Monthly figures are calculated on the basis of the yields on all the business days in a month. The annual figures are the unweighted means of the monthly figures. Adjustment of the scope of securities included on 1 May 2020. 2 End of year or month. 3 Source: Deutsche Börse AG. 4 Only debt securities eligible as underlying instruments for futures contracts; calculated as unweighted averages.

Source: Bundesbank calculations based on Federal Statistical Office data. **1** Annual figures based on the calculations of the Federal Statistical Office. Bundesbank supplementary estimations for the reporting years after 2011 that are not yet available. The quarterly figures contain numerous off-budget entities which are assigned to the general government sector as defined in the national accounts but are not yet included in the annual calculations. From 2012 also including the bad bank FMSW. **2** The annual figures do not tally with the sum of the quarterly figures, as the latter are all provisional. The quarterly figures for some insurance sectors are estimated. **3** The development of the types of expenditure recorded here is influenced in part by statistical changeovers. **4** Including discrepancies in clearing transactions between central, state and local government. **5** On the revenue side, this contains proceeds booked as disposals of equity interests and as loan repayments. On the expenditure side, this contains the acquisition of equity interests and loans granted. **6** Including central government liquidity assistance to the Federal Employment Agency.

Source: Bundesbank calculations based on data from the Federal Statistical Office and the Federal Republic of Germany – Finance Agency. **1** Particularly liabilities resulting from coins in circulation. **2** Besides direct loan relationships, claims and debt vis-à-vis other government subsectors also comprise securities holdings purchased on the market. No entry for general government as debt and claims are consolidated between different government subsectors.

Sources: Federal Statistical Office; Federal Employment Agency. * Annual and quarterly figures: averages; calculated by the Bundesbank; deviations from the official figures are due to rounding. 1 Workplace concept; averages. 2 Monthly figures: end of month. 3 Number within a given month. 4 Mid-month level. 5 Relative to the total civilian labour force. 6 Excluding government-assisted forms of employment and seasonal jobs, including jobs located abroad. 7 From January 2017 persons receiving additional income assistance (unemployment benefit and unemployment benefit II at the same time) shall be assigned to the legal category of the Third Book of the Social Security Code (SGB III). 8 Statistical break due to late recording of unemployed persons in the legal category of the Second Book of the Social Security Code (SGB II). 9 Initial preliminary estimate by the Federal Statistical Office. 10 Unadjusted figures estimated by the Federal Employment Agency. In 2020 and 2021, the estimated values for Germany deviated from the final data by a maximum of 0.1% for employees subject to social contributions, by a maximum of 0.9% for persons solely in jobs exempt from social contributions, and by a maximum of 28,1% for cyclically induced short-time work. 11 From May 2022, calculated on the basis of new labour force figures.

* Non-financial groups admitted to the Prime Standard segment of the Frankfurt Stock Exchange which publish IFRS consolidated financial statements on a quarterly or half-yearly basis and make a noteworthy contribution to value added in Germany. Excluding groups engaged in real estate activities. **1** Earnings before interest, taxes, depreciation and amortisation. **2** Quantile data are based on the groups' unweighted return on sales. **3** Annual figures do not always match the sum of the two half-year figures. See Quality report on consolidated financial statement statistics, p. 3. **4** Adjusted for substantial changes in the basis of consolidation of large groups and in the reporting sample. See the explanatory notes in Statistical Series Seasonally adjusted business statistics. **5** Including groups in agriculture and forestry. **6** From H1 2018 or 2018 onwards: significant changes in IFRS standards, impairing comparability with previous periods.

* Assets and liabilities vis-à-vis all countries within and outside the euro area. Up to December 2000 the levels at the end of each quarter are shown, owing to revaluations, at market prices; within each quarter, however, the levels are computed on the basis of cumulative transaction values. From January 2001 all end-of-month levels are valued at market prices. 1 Mainly net claims on TARGET2 balances (acc. to the respective country designation), since November 2000 also balances with non-euro area central banks within the ESCB. 2 Mainly long-term debt securities from issuers within the euro area. 3 Including estimates of currency in circulation abroad. 4 See Deutsche Bundesbank, Monthly Report, October 2014, p. 22. 5 Difference between External assets and External liabilities. 6 Euro opening balance sheet of the Bundesbank as at 1 January 1999.

XII. External sector

8. External positions of enterprises *

€ million

* The effective exchange rate corresponds to the weighted external value of the currency concerned. The method of calculating the indicators of the German economy's price competitiveness is consistent with the procedure to compute the effective exchange rates of the euro. A decline in the figures implies an increase in competitiveness. The weights are based on trade in manufactured goods and services. For more detailed information on methodology and weighting scale, see the website of the Deutsche Bundesbank (https://www.bundesbank.de/content/796162). **1** The calculations are based on the weighted averages of the changes in the bilateral exchange rates of the euro vis-à-vis the currencies of the following countries: Australia, Bulgaria, Canada, China, Croatia, Czechia, Denmark, Hong Kong, Hungary, Japan, Norway, Poland, Romania, Singapore, South Korea, Sweden, Switzerland, the United Kingdom and the United States. Where current price and wage indices were not available, estimates were used. **2** Includes countries belonging to the group EER-19 and additionally Algeria, Argentina, Brazil, Chile, Colombia, Iceland, India, Indonesia, Israel, Malaysia, Mexico, Morocco, New Zealand, Peru, Philippines, the Russian Federation, Saudi Arabia, South Africa, Taiwan, Thailand, Turkey, Ukraine and United Arab Emirates. The ECB suspends the publication and calculation of the euro foreign exchange reference rate against Russian rouble with effect from March 2, 2022 until further notice. For the calculation of effective exchange rates, an indicative rate is used for the Russian Federation from that date. It is calculated from the daily RUB/USD rates determined by the Bank of Russia in conjunction with the respective ECB's euro foreign exchange reference rate to the US dollar. **3** Annual and quarterly averages. **4** Euro area countries (from 2001 including Greece, from 2007 including Slovenia, from 2008 including Cyprus and Malta, from 2009 including Slovakia, from 2011 including Estonia, from 2014 including Latvia, from 2015 including Lithuania) as well as Canada, Denmark, Japan, Norway, Sweden, Switzerland, the United Kingdom and the United States. **5** Euro area countries (current composition) and countries belonging to the group EER-19. **6** Euro area countries (current composition) and countries belonging to the group EER-42.

Overview of publications by the Deutsche Bundesbank

This overview provides information about selected recent economic and statistical publications by the Deutsche Bundesbank. Unless otherwise indicated, these publications are available in both English and German, in printed form and on the Bundesbank's website.

The printed publications are available free of charge to interested parties and may be obtained through the Bundesbank's order portal. Up-to-date figures for selected statistical datasets are available on the Bundesbank's website. In addition, the new Statistical Series provide a new basic structure and advanced options for using data and are also available on the Bundesbank's website.

■ **Annual Report**

■ **Financial Stability Review**

■ **Monthly Report**

A list of the articles published in the period from 2010 to 2021 is available on the Bundesbank's website.

Monthly Report articles

September 2021
– The Eurosystem's monetary policy strategy
– The impact of the Eurosystem's monetary policy on Bitcoin and other crypto tokens
– The performance of German credit institutions in 2020

October 2021
– State government finances in 2020: deficit due to temporary effects of pandemic, escape clauses also used to build reserves
– The global economy during the coronavirus pandemic

– What do households in Germany think about the digital euro? First results from surveys and interviews
– The regulation of remuneration at credit institutions

November 2021
– The current economic situation in Germany

December 2021
– Outlook for the German economy for 2022 to 2024
– German enterprises' profitability and financing in 2020

January 2022
– Changes in the secured money market
– Climate change and climate policy: analytical requirements and options from a central bank perspective
– Scenario-based equity valuation effects induced by greenhouse gas emissions

February 2022
– The current economic situation in Germany

March 2022

– Monetary policy in a prolonged period of low interest rates – a discussion of the concept of the reversal rate
– German balance of payments in 2021

April 2022

– Potential macroeconomic consequences of the war in Ukraine – simulations based on a severe risk scenario
– Development of the debt situation in the euro area private non-financial sector since the outbreak of the COVID-19 pandemic
– Central government's debt brake: options for stability-oriented further development
– Demand for euro banknotes issued by the Bundesbank: current developments

May 2022

– The current economic situation in Germany

June 2022

– Outlook for the German economy for 2022 to 2024
– Pension insurance scheme: long-term scenarios and reform options
– Inflation-induced bracket creep in the income tax scale
– Public finances in the euro area: current developments and challenges
– The Bundesbank's surveys of firms – applications for assessing the financial situation in the corporate sector

July 2022

– Distributional Wealth Accounts for households in Germany – results and use cases
– Factors influencing international portfolio flows
– Cross-border interoperability of central bank digital currency
– Government debt in the euro area: developments in creditor structure
